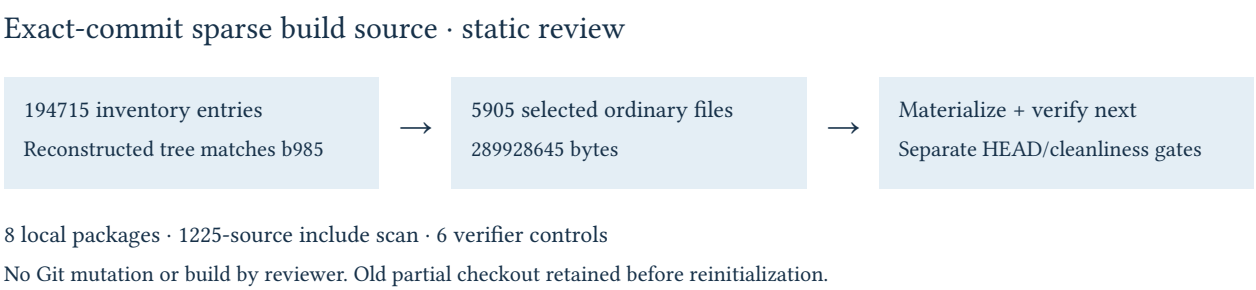
Independent exact-commit sparse-source review



Independent static review found no blocking discrepancy in the proposed sparse source selection for the unchanged ecbench build. No Git mutation or Cargo build was performed. The exact full inventory was independently reconstructed into Git tree895383ebc1fdc304045da79f3edc0d1e8a9979d8, matching commit b985ddb30b46abbd9a050e5753c7e301f40b07f6.

The partition has5905 selected ordinary files,289928645 bytes, and188810 omitted entries. Selected and omitted sets are disjoint and cover all194715 inventory entries; object IDs,modes and sizes match. All59 symlink/gitlink entries are omitted. Sparse patterns exactly equal the sorted selected paths with root anchors, contain no metacharacters and require non-cone mode.

All eight local package manifests were read from their exact Git blobs. Path dependencies close over the listed root/ seven packages; no local build.rs was found in that closure. Root examples/bin paths are retained as Rust sources. Optional five-leads uses root-level lib.rs rather than src/lib.rs; these Rust files are selected. The reporting feature does not activate its producer-only dependency.

The producer scanned1205 package-source files and recorded141 include expressions,140 resolved. The remaining hit at tournament_tests.rs343 is explicitly a runtime format-string fixture; its source comment and escaped string were inspected. An independent broadened lexical scan covered1225 sources, adding20 optional native root-level Rust files and allowing whitespace/different delimiters. It found no additional include hits or other embedding macro/OUT_DIR markers. This remains lexical closure evidence, not complete macro expansion or a successful build.

The verifier correctly checks each selected file with lstat, Git blob SHA1 identity and Git executable-bit mode, then records SHA256 and errors. Six isolated fixed controls exercised unchanged verifier bytes: correct file passes; wrong bytes, executable bit, missing file and file symlink fail; an untracked extra passes. Accordingly this checker alone does not establish exact HEAD, absence of omitted/untracked entries, ancestor symlink policy or effective Cargo configuration. Those remain the separately required root gates, as the proposal states.

The selection changes materialization only. It does not alter selected file bytes, algorithms, build feature arguments, cohort targets, seeds, protocol costs or execution budgets. Unconsumed historical artifacts are omitted from this build tree; this does not authorize omitting evidence from a research report. Registry dependencies and build scripts remain separately pinned by the unchanged Cargo environment.

Operational correction recorded from root: the previous checkout process terminated with status-2; Git cleanup removed its worktree administrative entry but left a partial destination and stale .git pointer. rev-parse reportedly fails128. The approved recovery plan preserves the partial directory under a retained name, then reinitializes the SAME intended source path with --no-checkout before applying these reviewed patterns. This review performed none of those mutations and does not treat the stale directory as a live worktree. No concurrent duplicate checkout is proposed.

Before build admission, root must verify the exact detached commit, selected hashes/modes using this script, tracked/ untracked cleanliness, omitted special entries and effective .cargo/HOME/CARGO_HOME settings. The existing bounded build owner/toolchain/receipt gates still apply. Build success, runtime image qualification and scientific execution are not established by this static review.
