Pivot/swap equal-row proof successor

Source-only repair after the retained failed native attempt. No compilation performed.

Equal rows: a = b

Substitute b ⟶ split i = a ⟶ substitute/simplify each branch

Unchanged statement and controls; compilation and independent review pending.

The prior compiler left a nested conditional in the equal-row case of swap_involutive. The successor explicitly splits i = a after substituting b. The positive case substitutes i and simplifies; the negative case simplifies using the inequality. The theorem statement and all other proofs remain unchanged. No axiom or sorry is introduced. Five compiler calls, seventeen readback names, all controls and import/runtime bindings are preserved. The attempt still reserves 900/600/900 seconds, totaling 2400, with unchanged resources and no automatic retry. The prior failed run and charge remain recorded separately. Fresh workspace and unit identities distinguish this proposed attempt. Actual prior debit and remaining allowance remain null pending final serial ledger binding; campaign ceiling and deadline remain 129600 seconds and 2026-11-11 noon UTC. Independent source review, publication and final release are required. This report contains no kernel success claim.
