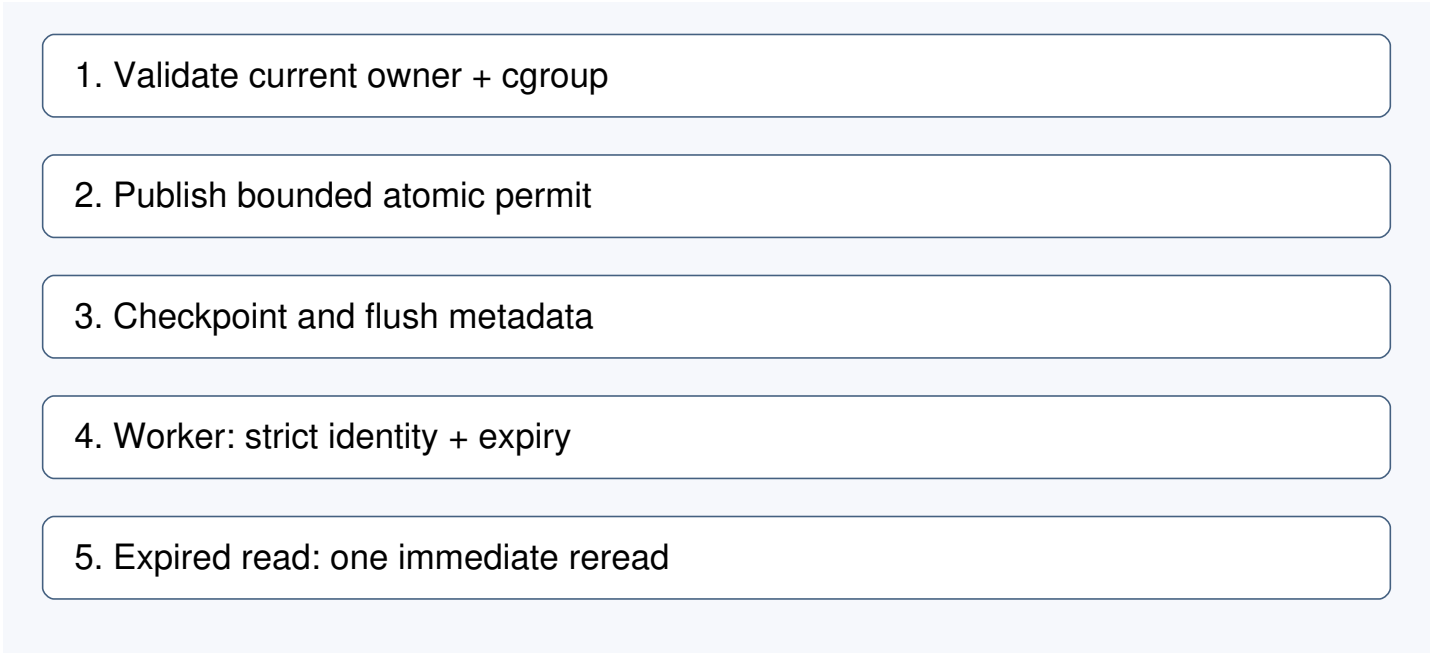
Root v4 permit source review



Status: source_review_passed_scoped

The corrected publisher verifies attempted launch, current invocation and nonempty matching cgroup before atomic permit publication and cumulative checkpoint. The worker retries exactly once only after expiry, with strict identity and final freshness. All three initial review findings are resolved in source and the 24-case prospective qualification.

Limits: 10-second permit; 15-second lease margin; single 1800-second validation; 2 CPUs / 16 GiB / swap 0.

Reviewer authored v3 ancestry but did not author v4. Review plan preceded source inspection. No compiler, payload or qualification execution by reviewer.

Required next bindings: actual qualification result, fresh post-v3 mutable-cache inventory, current ledger and lease, exact publication readback.

Machine-readable evidence: review.json, initial-findings.json, source snapshots and manifest.json. No measured runtime improvement is asserted.
