Runtime-only recovery: independent source review

No blocking discrepancy was found in the sealed recovery source and unadmitted template. Twelve producer files, seven recovery joins and nineteen original context entries match. Original base-client exit 0, retained IID readback and exact owner-tag image agree. Current IID metadata matches the stated root-owned 0600 single-link file.

The supervisor adopts the existing base after exact command, owner, context, image and layer checks. Its sole build loop is runtime. No base rebuild, pull, container, publication or image removal is present. One runtime attempt retains the existing 600-second total, 60-second readback reserve and 240-second build cap.

Scoped sudo-cat reads only the two permitted IID paths under the existing supervised client lifecycle. Deferred signals, uncertain ownership, exact-tag reconciliation and post-readback checks remain. Config.Env and ContainerConfig.Env are both redacted before persistent inspection output. No original receipt is rewritten.

The filled binding must change only prospective review reference and explicit admission against the template. Actual image rechecks and runtime qualification remain future steps. The source review made no Docker/build calls.

Reviewer authored the original assembly supervisor and route packet, but not this additive recovery. This involvement is disclosed; separate original-source and final-provenance reviews remain bound.
