Twist index calculus: checked accounting

Historical partial panel; 25 October 2026. No new solve or timing admission.

The native accounting tool re-read the already committed 29-exit snapshot. Nine configurations in that historical snapshot have first-run audit and two deterministic A/A checks. The comparison below uses the two complete four-arm groups at p37, seeds 0 and 1. The remaining p37 seed-2 zero-phi configuration is retained in the JSON, without inventing its missing controls. Later panel completions are excluded from this historical analysis.

Seed 1: preprocessing, online work and rank

Arm	Zero F4	Target F4	All F4	Queries	Zero rank	Final rank
plain φ	0	144	144	2	0	3/3
plain [2]	0	144	144	2	0	3/3
zero φ	82	72	154	1	2	3/3
zero [2]	216	144	360	2	1	3/3

At seed 1, zero-phi reaches full factor rank before the target and uses one target query where plain phi uses two. Its recorded zero plus target F4 system count is 154 versus 144 for plain phi. At seed 0, all four arms already recover after one target query. This separates an observed online rank effect from the preprocessing charge. Neither observation determines complete end-to-end cost.

Scope: these are public synthetic known-answer workloads and presentations, not independent secrets. A finite-system count is a diagnostic, not a common operation price. Every full-panel and complete-price obligation remains open.

Relation yield and arithmetic coverage

Seed 1, same verified configurations. Signed target tuples and projective matrix rows count different objects; they are not interchangeable relation yields.

Arm	Zero signed	Target signed	Projective rows	F4 row muls	Online Fp muls	Cold Fp muls
plain φ	0	4	4	17,026,817	2,776,060	4,954,250
plain [2]	0	3	3	16,687,744	2,727,297	4,055,275
zero φ	48	2	4	17,510,778	2,187,743	12,224,047
zero [2]	24	3	4	41,068,849	2,727,297	11,507,181

F4 row multiplications and native Fp multiplications cover different code. Group calls also contain lower-level arithmetic; their counters cannot simply be added to field counters as another independent primitive price. The JSON retains these vectors, allocation observations, RSS, exact count ratios and all three raw diagnostic intervals for every verified configuration.

What was checked

The tool binds records to independent audit and parity hashes, requires all three registered executions to have exit 0, checks exact deterministic A/A equality, recomputes counts and cross-checks the frozen panel reducer and independent rank/point checks. Three native tests cover journal allocation, missing/non-telescoping intervals, duplicate rows and undefined ratios. The actual partial-as-complete control must reject before creating output.

The eight phases telescope to the charged cold interval. The reusable and online intervals also telescope. The two journal portions are derived from that recorded cut; all journal time is not assigned to the online interval. The clocks remain raw shared-host diagnostics and are not used for speedups.

What remains unresolved

Complete end-to-end prices remain null. Missing items include non-row F4 work, unmetered primitives, memory/hashing/journal costs, and calibrated scalar and group prices. Full-panel completion, final input/source seals, native reduction replay, archive publication, admitted timing and strongest matched IC/rho controls remain separate obligations. This re-analysis does not modify the two frozen producers, their workload or managed owner.

Reproducibility

Native tool: `postprocess/native`; raw check: `runs/phase2-accounting-v1`. Compact results: `results/phase2-accounting-v1/accounting.json`. Source snapshot: `results/phase2-live-progress-v1/summary.json`.
