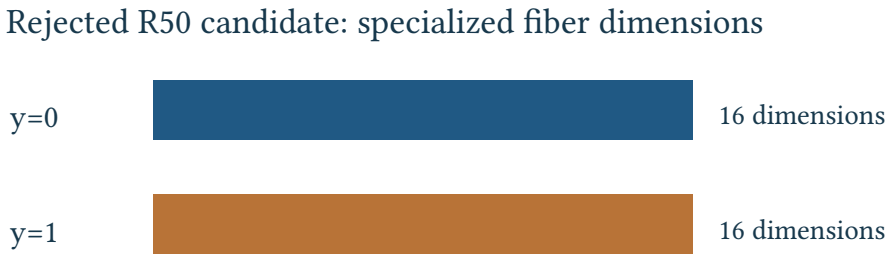
R79: bounded u=0 probe of the rejected normalP candidate

The retained R50 finite-u candidate has 22 variables and 400 relations. After specializing $p = 0$, its $y = 0$ and $y = 1$ quotient fibers are both finite of dimension 16 over F2; the respective R78 source factors reduce to zero. Their dimensions account for the full degree-32 budget.



Attempt 01: parser error retained. Attempt 02: accepted, source factors vanish.

Candidate-only result; no normality or branch-ramification certificate.

The first run was rejected by the strict error gate after Singular parser errors at an ideal constructor. Its raw log is retained. The frozen repair passed exit 0, exact marker, zero-error, 12 historical byte pins and six donor hashes. The result is a diagnostic of a previously rejected normalization candidate; its reduced factors and normality remain to be checked before any branch claim.
