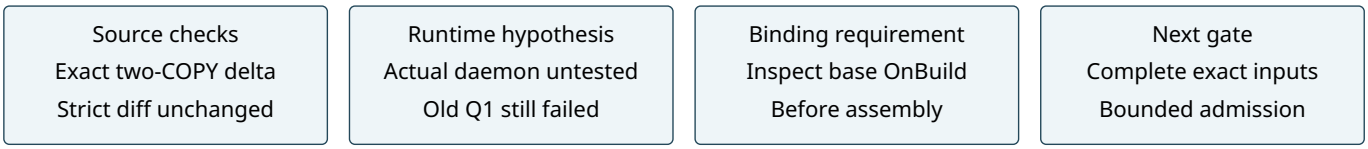
Independent runtime mountpoint source review

The non-author reviewer found the exact recipe delta faithful to the source proposal at commit 0de65e421b. Runtime effect remains untested. This packet preserves the separate review, exact inputs and mechanical source checks; no build, Docker operation or qualification retry was performed.



Verified source facts. The patch adds a comment and two COPY instructions with root ownership. Both inputs are zero-byte nonexecutable Git blobs; observed checkout modes were 0644. Old/new recipe hashes and patch match bindings. The unchanged qualifier retains its strict rejection of every nonempty writable-layer diff. Its active-case source checks reject missing or incorrect fixture/gate bind mounts before starting the container. The original Q1 record remains failed, with only Q0 passing and cleanup complete.

Runtime hypothesis. Preexisting destination paths may avoid the three observed Docker diff additions, but the actual daemon/storage-driver behavior and resulting metadata have not been tested. Source inspection does not establish an empty diff or qualified image. Actual ancestor path types, permissions, ownership and possible inherited conflicts must be inspected for the exact bound image/context.

Pre-build binding requirement. The proposal still has an unbound BASE_IMAGE. Before any assembly, inspect the exact base configuration and require empty OnBuild as the historical assembly plan already specified. Docker documents that inherited triggers execute when processing downstream FROM and are then cleared from the final image; a post-build empty-OnBuild check alone therefore cannot establish that no trigger ran. Primary source: Dockerfile reference, https://docs.docker.com/reference/dockerfile/#onbuild. The two added COPY instructions introduce no RUN command, but do not replace this base check.

Next admission inputs. Bind exact base/configuration, context members and modes, recipe and builder inputs; reconcile existing image/container ownership; preserve old identities and failures. Any new assembly and qualification need their own bounded admission and a new final image identity. The source review renews neither the historical one-attempt software allowances nor the expired scientific campaign. No runtime pass or cost ratio is inferred.

Review scope. The reviewer authored neither the recipe nor its claim, read no sibling new reports, and disclosed inherited context. Exact source-read attestation and official Docker references remain in review/REVIEW.md. The result is source review complete, pending bindings and runtime qualification; it changes no scientific status and preserves all 1,260 targets.
