SAME actual completed kernel / first jet
Derived c != 0, w=v2(c), normalized R
Rows agree mod 2^v
Actual denominator ratios == 1 mod 2^(v-u+1)
One literal port per retained residue
Actual minor M == identity mod 2
Finite-product determinant congruence
det M != 0; rank M = 2^u
Literal row representatives
2^v integral factors; residual w+v-u+1
Any rational factors at residual w+1
need at least 2^u columns
At the lowest bit: 2^u is necessary and sufficient
No minimum 2^v claim at higher precision
OPEN: smaller higher-precision moment profile,
all chart jets, full recursive/public-input cost
