Resource diagnostics — original prover retained

29 October 2026. These development invocations investigate the known P-192 prime-proof stall after actual attempt 001. They do not run the point-trait comparison or fit historical labels. Commands, exact source, logs, status files and binaries are retained in evidence/diagnostics/raw.tar.xz; SHA-256 002543ff44ebdd811219810d9709961e8473c365ea403b3dc880e8c18b3b40e3, 14,888 bytes. The observation records every result. All ran on the same shared local host; no performance clock is admitted.

Five invocations were planned, attempted and recorded: two timeouts, three completed, none resumed or excluded. Primitive 001 uses the original generic prime proof at 768 MiB, 15 seconds: status 124, stopping after the pre-primality stage marker. Primitive 002 uses APRCL at 768 MiB, 15 seconds: status 124. Primitive 003 confirms the integer representation and known 192-bit input, then completes the original prime/group/bit primitives at 1536 MiB: status 0. Primitive 004 runs the exact unchanged 001 binary at 1536 MiB: status 0. The fifth native invocation proves all 21 known p/n pairs across six sizes at 1536 MiB with a 60-second watchdog: status 0. Physical container allowance was 16 GiB; virtual address limits are different resource quantities.

The same-binary resource observation justifies an explicit protocol amendment for execution. It does not establish a general PARI memory threshold, a weak curve, original resource policy or historical rejection. The production algorithm and its prover are unchanged; the timed-out APRCL diagnostic was not adopted. See the official PARI isprime documentation and the amendment. No probable-prime replacement was used and no partial trait matrix was admitted.

The figure shows the five invocation outcomes, not performance ratios. The frozen version 1 timeout remains a separate failure. Version 2 was frozen and committed before the successful full run; this report does not retrospectively alter its limits or discard a curve.
