PKM Kummer tower m = 3, N = 21: msolve -t 16 (Amendment A1, minimal P2)

Run 20261018T2208Z, pod `dapncaphacx5w3` (16 vCPU, 128 GB). System `m3_t7_x221026520` (target 0).

system	outcome	wall	peak RSS	rounds
control m3_t5 (N = 15)	exit 0, answer identical	245.9 s	2.0 GiB	as committed
m3_t7 target 0 (N = 21)	exit 139 in first degree-8 round	7,088 s	99.6 GiB / 108.8 GB cap	27 done, 7 at degree 7

Recorded. The F4 trace equals the single-thread run round for round. Degree 7 ran out of pairs without reaching the unit ideal; msolve then selected 398,409 degree-8 pairs and died inside that round before reporting `new`.

Reading (A1.4, frozen). Inconclusive: no productive degree-8 round, memory stop, one target only. The question needs the same system and target 1 on a host where the first degree-8 round fits (256 GB or more per process).

Not claimed. Not H0, not a plateau reading, not a cost row or an improvement.
