Independent strict-storage and field-algebra reviews

Two separately assigned reviewers completed fresh replay and source-fidelity review under the prospective plan at commit 660bbb72be. Both report machine passed and faithful scoped correspondence for their named claims. This archive records technical review, without an official hypothesis transition.

Strict-storage review. Four declarations at e45227d1b8 preserve the actual generic fallback Run relation and export both list normality conditions, nonempty support and length(V)<length(U). Six modules and six named producer readbacks passed. Two producer controls and four additional reviewer controls check empty support, non-normal [0], decoded zero versus empty storage and exclusion of a zero residual for degree-five f. The false theorem was rejected, as were three malformed checker inventories. No unexpected Lean failure occurred.

Field-algebra review. Five field CRT declarations at e45227d1b8 and nine quotient-shape declarations at 660bbb72be passed fresh replay in seven modules with 24 named readbacks and ten fixed controls. The false theorem was rejected, and six checker mutations were rejected. Coefficient orientation, Bezout coefficients, product residual divisibility, cubic interpolant, quadratic quotient and the negative monic scaling factor match their stated source formulas. Controls include zero norm, zero slope, repeated support, sextic cancellation and omission of the minus sign. No unexpected replay failure or source mismatch was found.

Hypotheses. Strict storage retains canonical word inputs, prime modulus, the explicit bound below 2^31, input validity and degree-five curve polynomial, within the stated n=1/no-diagnostic-table native dispatch. The field claims hold over arbitrary fields, with nonzero norm and nonzero slope wherever the degree claim needs them, plus the two input residual divisibilities and degree-five f. They do not require curve smoothness for these polynomial statements.

Verification custody. Both reviewers generated fresh target module caches and compared sources, helpers and compiler bindings before and after. Standard-library and Mathlib union caches were reused and hash-bound, not independently rebuilt or kernel-rechecked. In strict review, 216 of 217 copied helper sources match pinned archived blobs; the remaining generic Readback source is preserved and verified outside the actual local import closure. The archive omits compiled caches and native checker executables, retaining sources, commands, raw logs, inventories, source mappings and binding receipts. Large binding files are retrieved through the artifact store.

Independence. Each reviewer owned one separate joint, authored none of its reviewed components and reports no sibling-review access. Both inherited historical context; neither review is labeled blind re-derivation. The prospective plan stated that boundary. tools/check_review_independence.py is absent from both the working tree and tracked file inventory, so no automated attestation-checker pass is claimed. The two JSON records retain individual outcomes and source-read attestations.

Scope and next construction. The field review predates the separate word-batch-inversion packet at 5937d99b29; its conditional native inverse statement is retained as reviewed, rather than retroactively expanded. Remaining composition work includes exact word slope coefficients and inverse_lead, polynomial-call correspondence, final remainder/storage and divisor-class interpretation. No cohort, timing or new cost result was produced. The 1,260-target scope and campaign deadlines remain unchanged.
