Historical skip criterion: source check

27 October 2026. **No supported criterion explaining every omission was found.** The current primary accounts and the connected repository records checked in this round still lack the original generator, point-counting inputs and candidate decision trace. That prevents attributing a fitted rule or an observed trait to the historical program. It does not prove that no such criterion or archive exists.

What the sources establish

The Anthropic account still lists the omissions as an open question. It reconstructs the seed stream, not a candidate-by-candidate acceptance log. The Valsorda reproduction records an order-bit-width condition, but explicitly leaves an additional selection step unexplained. These are source statements, not new arithmetic results here.

The 18 October TLS message proposes interrupted computation or later human selection as possibilities. It supplies no decision trace establishing either possibility. The current thread index and targeted web searches supplied no new original program or supported complete rule. Search coverage is bounded and indexed results can be incomplete.

The retrieved prior draft audit, pinned at 351c9c021c7be044ade54dc7e352b33d3a772244, reports that the recovered November 1997 X9.62 draft gives no additional predicate separating the eleven named omissions. Its prior acceptance audit reports a broader 69-position draft-compatible prime-order cohort. These are prior results with their original provenance; neither was recomputed here. They also do not show which positions the original program visited. The current 21-row comparison remains a fixed, explicitly scoped dataset.

Result and remaining dependency

Neither a security weakness nor the historical reason for all skips is established. The earlier complete factorizations, exact embedding checks, period-software trials and conditional work-counter proofs remain unchanged. Their evidence is in the work report and factor follow-up. No new legacy execution, point count, DLP, benchmark or mathematical theorem ran in this source check. The diagram marks missing evidence; it is not an attack graph.

The specific dependency is an authenticated acceptance mechanism and its relationship to these stream positions, or a mechanism with independently testable historical predictions. A recovered program or log would need exact curve identities, root choices, actual point-count inputs and outcomes, candidate visitation, RNG consumption and the keep/reject reason. A fresh label fit alone does not meet that requirement. Original records were neither supplied nor found in the checked scope.

Search scope and provenance, the two pinned reports and the rendering source accompany this PDF. This is a literature/source update, not an experiment or an independent replay of prior results. It adds no attack, isogeny, timing or IC/rho value to the canonical graphs. The historical criterion and both weakness hypotheses remain unresolved; no research job is scheduled.
