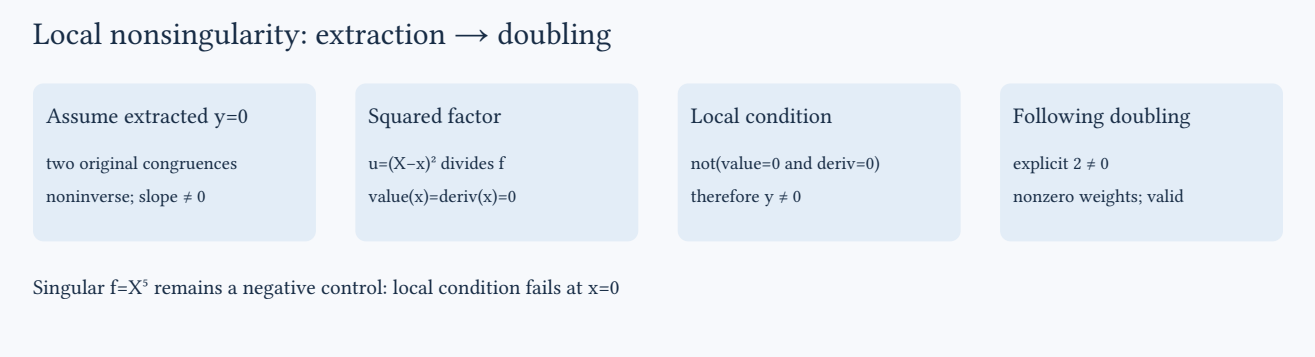
Same-support extraction: local nonsingularity bridge

Four compiled lemmas derive the exact condition needed to continue from extraction to doubling.

If the extracted ordinate is zero, original congruences and the noninverse/nonzero-slope premises force $u=(X-x)^2$ and $(X-x)^2$ dividing f. For the source monic quintic, the tangent remainder then forces both value(x)=0 and explicit derivative(x)=0.

The local premise NOT(value(x)=0 AND derivative(x)=0) excludes that case. With characteristic different from two, the weighted extracted point has nonzero raw y and the following doubling has nonzero weights and normalized validity. No output-validity assumption is added.

The condition is local and explicit; no global squarefree bridge or abstract derivative-library equivalence is claimed. Source normalized guard premises remain separate from raw-word reflection.

Final main, fixed controls and four-theorem readback pass. A full nonunit positive fixture checks extraction through doubling. Singular $f=X^5$ at x=0 remains a counterexample without the local premise. Earlier proof and control preparation failures are preserved.


Independent review pending. No root edits, scientific runs or cloud actions. This is a conditional field-value component; cost ratios remain null.
