NIST controls: review qualification

Reviewed head: 03e4a7d7609e5dc3d406d58bf44f606410f9a78a

The retained 9,015 rows reproduce all 15 metric summaries and the recorded accuracy and parallelogram gates. The original artifacts and protocols are preserved; hashes and the independent Rust replay are in this directory.

Factoring: two budgets, incomplete residuals

There are **7,200 control values overall**: 2,400 per curve. M1 is unchanged after the recorded ECM supplement in all 7,200 comparisons, and 150 planted positive controls pass. This establishes agreement under the two recorded budgets. It does not certify complete factoring or invariance under any factoring budget.

Curve	Controls	Unsplit composites	Positive controls
P-192	2,400	1,301	50/50
P-224	2,400	1,475	50/50
P-256	2,400	1,592	50/50

The 4,368 unsplit entries have no retained certificates excluding all factors below 2^32. Target comparisons remain finite-budget observations.

Heights: near-zero numerical values

The claimed 59–66 percent zero pairings correspond to a descriptive threshold of absolute cosine at most 1e-12. The stored floating-point zero counts are smaller. Neither category establishes an exactly zero canonical pairing.

Curve	Pair controls	Float zeros	At most 1e-12
P-192	500	82	296
P-224	500	101	328
P-256	500	148	306

Five doublings and floating-point logarithms were used. The frozen checks pass, including maximum parallelogram defects of approximately 0.001354, 0.001354 and 0.002708 nats. These are instrument checks, not rigorous error bounds on every pair or certificates of exact logarithmic identities. Conservative empirical ties and the original finite-sample decisions replay correctly.

Boundary of this review

This is a statistical replay of stored rows, not independent recomputation of factoring or rational heights. The lost first attempt and complete cross-attempt accounting are not reconstructed. No new research run was launched. See README.md, replay.json and original-artifacts.json for scope, counts and provenance.
