Result: N83 K = 16,627 selector-only control

Run: 2026-10-18 09:21:26–09:26:49 UTC. **Result:** `PASS_THREE_CHECKED_ARMS`. The exact four-summand model had 201,598 variables, 5,915,238 clauses and 3,901 XOR rows before x and choice units. A1 and A2 pinned four representative selectors and 28 phase-zero bits. B pinned the selectors while leaving all phase bits free. All three returned the same checked rank-one relation for public indices `[0, 166, 332, 498]`.

B's SAT call took 6,487.732878 ms with 517 completed decisions, 222 conflicts and 826 completed XOR passes. A1 and A2 took 10.045541 and 17.313917 ms, with zero decisions and three passes each. Worker walls, including retained-base import, were 38,614.439768, 42,786.035270 and 36,311.395725 ms. All three one-CPU, hard-4-GiB, zero-swap containers exited normally without OOM. The separate native verifier replayed each relation and rejected changed-x and changed-row receipts. B returned before its cap, so the frozen conditional phase-only C arm was omitted.

This is a constructed-witness solver-stage result. The worker did not export SAT assignment bits, and the separate verifier shares the library's field and curve arithmetic. Natural relation yield, useful rank, a selected prebuilt base across m = 2, 3 and 4, complete cold IC cost and matched rho remain open. See `RUN_REPORT.md`, `summary.json` and `raw-files.sha256` for exact sources, commands, receipts and accounting.
