Publication custody audit

Publication custody and static contract audit

Initial hashes: 1715 / 1716 — one producer-map name collision

Scoped repair: 53 / 53 affected entries match; original mismatch retained

Aggregate links: 17 / 17; canonical Lean targets bound: 19 / 19

66 local cache candidates; zero in tracked or included publication set

Box<Actual>: one-line storage change; static JSON shape unchanged

No build/test execution. Live boxed-check results excluded.

Custody repair The initial pass found a producer custody-map copied under the same basename as its new publication map. Root restored the original under producer-custody-map.json and recorded the correction. All53 included entries in that affected map now match; the initial mismatch remains retained. Other initially matching entries were not rehashed after repair.

Canonical source bindings All19 registered modules match retained snapshots. Constructor and Add11 use only the explicitly documented terminal-newline normalization; original reviewed bytes remain retained. This is source custody, not a new proof compilation.

Publication set None of66 local compiled/render-cache candidates occurs in the1,957 narrowly enumerated tracked paths or is claimed included by a custody map. Local build caches remain present. Render source and log receipts are distinguished from compiled caches.

Static JSON contract The exact change against da1464 is actual:Actual to actual:Box¡Actual¿. Resolved Serde forwards deserialization to Actual and wraps the result, preserving JSON fields, tags and rejection policy. Boxing changes storage/allocation. No dynamic validation is inferred; root's live boxed-request checks were excluded.

Artifacts REVIEW.md preserves source analysis; status.json, custody-checks.json, canonical-bindings.json, aggregate-links.json and postrepair.json retain exact scope and receipts. No repository edits, builds, tests, cloud actions or scientific execution were performed by this audit.
