First actual finite-count proof check

Run uniform-lean-v2 begins 2026-10-24 01:44:51 UTC after recovery of the interrupted empty v1 launcher. The gate compiles the actual finite-count theorem source, not an assumed statement or an unchecked native result.

The compiler exposes an unresolved goal in the inductive counting proof: 1+ks.length=ks.length+1. The build fails and its downstream declarations show sorryAx; they are not accepted as proofs. The failed source text, log and source hash remain in runs/uniform-lean-v2/.

The repair supplies addition commutativity explicitly. The next v3 build is separate. Every residual label being less than n remains a stated hypothesis; no domain-size, image-injectivity or uniform historical-sample assumption is silently added. This is one-worker, 8 GiB, bounded proof verification, with no performance result or quantitative plot.
