Prime61 root and enumeration pilot

The frozen four-cell $n = 61, m = 2$ prime-field plan completed on modulus $2^{61} - 1 = 2305843009213693951$. Both bounded enumeration cells produced verified method artifacts; both root cells reached their predeclared timeout. All four attempts were retained and exported. Independent ECDLP scalar solves: 0.

Outcome counts (two twists per method)

Method	Verified artifact	Timeout
Root	0	2
Enumerate	2	0

Root timeouts:  2/2

Enumeration verified:  2/2

Evidence and limits

The independent audit checked archive hashes, native manifests, modulus, method, twist and status for all four cells. The pinned official export checker reported zero findings: four planned and attempted, two completed and two censored. Fresh S3 reads and hash checks independently sampled archive indices 0 and 3; producer readback receipts cover all four archives. The frozen protocol and plan preceded all attempts. Native work limits were 30 seconds per cell, 90 seconds per outer call, 2 GiB memory and 64 MiB trace.

This bounded pilot establishes method-artifact and custody evidence for these four cells. It does not compare method speed or determine an exact fall degree. The machine-readable report and evidence links are in `report/run.md`.
