p739 retained cross-session audit

Observations only. This report records a native, solver-free comparison of two preserved sessions. It makes no timing, ratio, admission, or scientific-priority judgment.

Recorded comparison

Quantity	Count
Records in each session	1080
Exact deterministic solver/accounting projections	1080
Measured rows replayed identically by each retained audit	900
Warmups statically verified and cross-session compared	180
Disallowed differing paths	0
New solver executions / measurements	0 / 0

Hash-bound result

Normalized plan SHA-256: `6627fb44589dacd3d79b8d28fdf0fb0df523cb53e3258b9713519a22439ff932`
Normalized specification SHA-256: `523a99e19373bd205acd954bab9549e7fbe59830fd7273658f2b8f01eede3b8a`
Deterministic projection SHA-256: `91338d7abcda1144d949d64d827de81d874ca49d07a2b536cd803f42ff78a3e1`
Projection bytes: 12286741.

The row mapping and complete input bindings are in `row-mapping.json` and `audit.json`. The comparison pairs exact unsigned 64-bit seeds; it never converts them to floating point. Every observed difference is checked against a fixed leaf-level allowlist before the deterministic solver/accounting projection is formed. An unlisted or newly differing field causes failure. The projection excludes wall and CPU timing, maximum RSS, faults, context switches, scheduler CPU observations, IRQ observations, isolation/environment fields, and session/record identities. It therefore does not establish equality of all non-wall or all resource content.

Fresh audit-receipt provenance

The compared fresh audit is the exact retained bytes of one named, versioned remote result object. Its own timestamp is after session completion, its binary and environment identifiers match the fresh session, and the downloaded SHA manifest binds the same bytes. These records do not establish a separate auditor principal or process.

Review limits

- Both sessions used the same measurement binary; this is not an independent implementation check.
- The 900 measured rows were replayed identically by each retained ecbench audit receipt; 180 warmups were statically verified and cross-session compared but were not replay candidates.
- Timing, isolation, environment, session IDs and record IDs are excluded; this does not validate wall time, admit ratios or qualify either session for a timing claim.
- Excluded process-resource observations include maximum RSS, faults, voluntary and involuntary context switches, scheduler CPU time/CPU identity, IRQ observations, and user/system CPU time. No equality of complete resource costs is claimed.
- The fresh receipt is version-bound and post-session, but the preserved evidence does not establish an independent auditor principal or process.
- This software audit changes no frozen protocol, record, plan or measurement artifact.
