Root materializer admission review

Independent prospective source review

5 November 2026

Disposition: source adequate for bounded materialization. Exact published producer `b2cb81962e30`. No materializer or compiler execution occurred in this review.

Bindings checked. Packet hashes and published Git bytes match. All eight input hashes match; materializer and helper equal the independently reviewed sources. Task 1656 epoch 1 and attempt match. Workspace, output and unit were absent; cache directories exist. Available local workspace was 99.5 GB. Recheck these mutable facts immediately before launch.

Ownership. Norm V3 records all three terminal owners, although its compiler phase failed. The new unit uses RemainAfterExit=yes: a successful payload remains active(exited). Parent must stop that captured invocation and verify terminal state plus empty or absent cgroup. Launch-client exit zero is not native success. Journal fallback requires exact privileged same-boot/unit/invocation start and success records.

Limits. Two CPU, 4 GiB, zero swap, 512 tasks. Worker 880 seconds; systemd 885 plus 5 stop; GNU 895 plus 5 kill; parent 900 seconds total including capture, wait, cleanup and sealing. One attempt, no overlap or automatic retry. Manual supervision is an explicit dependency, not a newly verified automated wrapper.

Accounting. Remaining 43,200 seconds reserves 900 materialization and 1,800 separate validation, leaving 40,500. Deadline remains 6 November 2026 04:00 UTC; waiver concerns dollar facts only.

Evidence boundary. Materialization must produce the real input manifest and hash before separate full-library validation admission. No such native digest is claimed known now. Parent publication, exact lease readback and owned terminal proof remain required. No source blocker found at this scope.
