Same factor base B, same coefficient candidates C
change the actual problem
Actual twist injection psi: E_d(k) -> E(K)
Matched base psi(B); target is the minus image
Different rational groups or factor-base constraints
Whole-group raw rate = 1 / group order
Arbitrary small-base useful rate needs evidence
Solver degree D and work model
M(n,D)=binomial(n+D,n)^omega
No claim D is lower merely because of twisting
Identical accepted coefficient sets
Same raw/useful yield and coefficient-row rank
Kernel-checked
useful-rate input
per-attempt work input
Conditional total budget
O + required_rows * attempt_work / useful_rate
Setup + transfer + LA + descent + verification in O
Faster iff overhead increase is below collection savings
Kernel-checked inequality; not a measured speedup
To solve the original main DLP:
verified scalar-preserving injective subgroup reduction
and charge its entire cost
