Concrete filled assembly binding review

No blocking discrepancy was found in the exact supplied binding. Ten binding hashes, eleven retained artifact entries and fifteen runtime members match. The final ecbench binary joins the corrected-source build receipt and separate final provenance review.

Actual revision/tree, target, default-feature selection, rustc output and RUSTFLAGS match. The build-info timestamp exactly represents the recorded build-end time. The retained owner and immutable parent hashes also join their receipts.

The independent supervisor review accepts this exact source. The local route review establishes observed legacy routing and the cached-parent contract at the reported commits. The supervisor still rechecks actual parent presence and daemon identity; no concurrent cache removal is assumed. No network-denial claim is inferred from the pull flag.

The binding remains admitted=false. This review covers the intended one-field admission change only, after root acceptance; other edits require reconciliation. Assembly produces local image identities for subsequent qualification.

Reviewer involvement. I produced the supervisor and route packet, but not this filled binding, final build or independent source/provenance reviews. This is a binding and custody review, not a second independent source review of my own supervisor.

No Docker, build, container, cloud or native payload action occurred. Existing caps and uncertainty handling remain. The exact binding hash, checks and scope are retained in review.json and checks.json.
