Proposed exact mount-diff contract

Pure parser checks passed; independent prospective review pending.

The retained v5 qualification failed its empty-diff assertion after Q0 passed and Q1 produced its expected output. The observed additions were `/fixtures`, `/qualification`, and `/qualification/exec-gate`. That failure remains unchanged.

Proposed amendment

Accept exactly those three additions, in any order, after the existing identity and read-only mount checks. Reject all other filesystem changes. This changes the contract explicitly: it does not establish an empty writable layer or identify who caused a change. No supervisor integration or new qualification was executed.

Fixed checks

All 27 predefined cases had their expected outcome: six permutations accepted and 21 negative cases rejected. Negatives cover empty, missing and duplicate entries; changed/deleted entries; an extra child; altered prefixes/suffixes; dot paths; whitespace and framing variations; non-ASCII, NUL and oversized input. The retained native diff also parses under the proposed contract.

Scope and next review

The parser is pure Python with no socket, Docker, process-launch or cloud capability. Independent review must assess whether this amended filesystem contract is adequate, how it joins the existing identity/mount checks, and whether additional metadata observations are required. The scientific campaign remains expired; no worker-time admission or scientific result follows from these checks.

Primary documentation: `https://docs.docker.com/reference/cli/docker/container/diff/`. Docker defines A, C and D as added, changed and deleted, and measures changes since container creation. That documentation does not assign writer attribution for this observation.

The accompanying `checks.json` gives every fixed case and input hash. The original native receipt and diff are bound in `bindings.json`. The diagram is provided as editable SVG.
