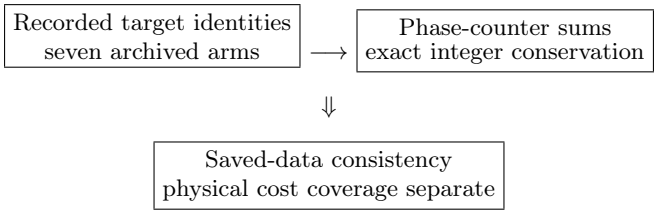
Saved phase-counter conservation

A fresh native read-only check joined the seven archived factor-base and projective-law arms to their named raw records. Each arm retains all 1,260 standardized targets, with distinct standardized keys and matching bit size, prime, target index and workload identifier.



For every one of the 8,820 candidate records and its rho record, each recorded aggregate counter exactly equals the sum over its named phases. Counter keys must agree, all values must be unsigned integers, phase names must be unique and phases must be nonempty. No issues were returned.

One coherent control passed; five deliberately broken cases were rejected: a dropped phase, an altered total, duplicate phase name, negative counter and empty phase list. The final implementation additionally rejects repeated standardized identities. All input file hashes were rechecked unchanged after the audit.

This checks conservation of recorded counters. It does not authenticate their original execution, recompute an elliptic scalar, establish that instrumentation counted every physical cost, or supply wall-clock phase timings. No new price ratio is produced. The full target request remains unchanged.

Commands and outputs are retained for two native builds and reads. The second adds standardized-key uniqueness and bit-size agreement; result.json is the earlier narrower check and result2.json is final. No scientific generator, solver, or cloud job was launched.
