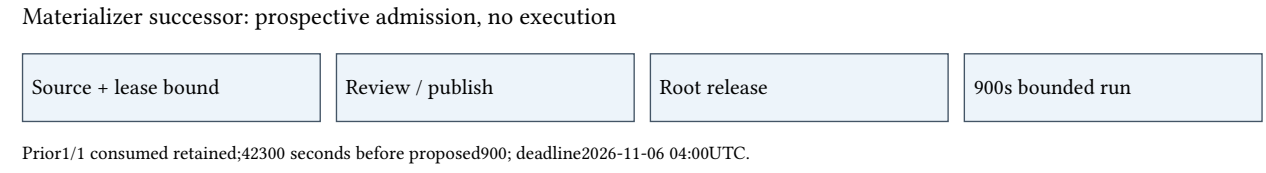
Bounded materializer successor admission

One prospective new900-second attempt is allocated within the existing46800-second campaign. Historical4500 seconds remain charged;42300 remain before the new attempt,41400 after a full900 charge. Deadline2026-11-06 04:00UTC is unchanged. No worker has executed in this version.

The exact worker is the published native-limit-gate candidate8609dfee (SHA2564e01f95cde6fe851a656819133ff22cf0b65d20e39fe9227ee6bce24ba557b71), with unchanged safety helper. T1716 binds actual fresh runtime paths, unit and live lease/fence. Local input-file hashes match, proposed directories are absent, and unit readback reports not-found. These observations must be repeated at release.

The worker keeps2CPU,4GiB,zero swap and512tasks; native880seconds, manager885+5 and timeout895+5 remain within900 total. Its native AS/DATA policy records actual limits and rejects finite soft/hard values before child commands without changing them. Failure and owned cleanup receipts remain mandatory.

AUTHORIZATION-AUDIT.md preserves the distinction between user ceiling/deadline and assistant-authored per-plan attempts. A dated prospective amendment may be coordinated within existing execution authorization; it does not silently renew the old1/1 plan. Historical evidence and inert drafts remain unchanged. Root release is still required.


Independent source review7362ee80f42dffe99089520d8dc6809293152d30 is published and confirmed by GitHub API. reviewed=true refers only to that source review. Exact command/config review and admission publication remain pending with null fields; launch_disabled=true remains. No native input manifest or limit values are invented. Full root validation remains a separate1800-second admission after actual materialization, preserving four exact controls and the full library suite.
