Independent tripling field review

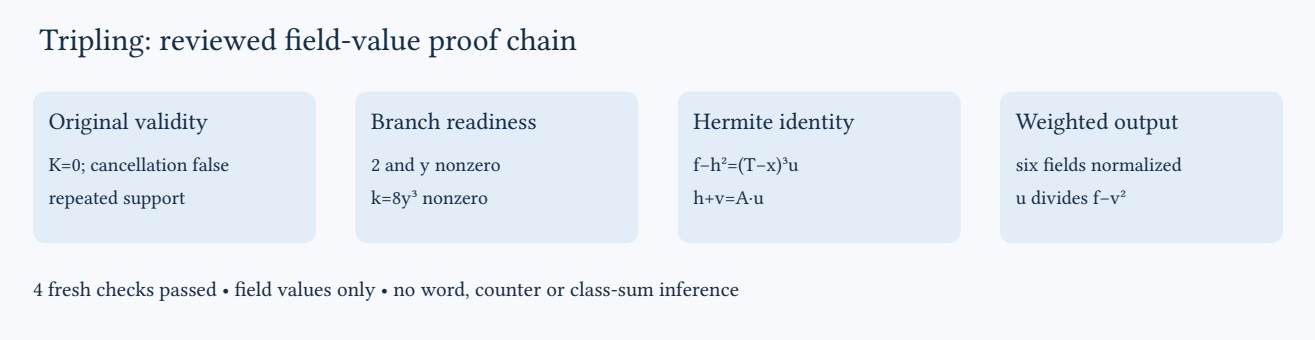
Result: validated at the weighted field-value scope.

Original valid point/divisor premises and actual repeated-support branch guards imply nonzero output weights and normalized Mumford divisibility. Source inspection matched all six output expressions; triple has no internal conditional.

The derived gate is $2 \neq 0$ and $y \neq 0$, giving literal $k = 8y^3 \neq 0$. No derivative-nonzero or output-validity assumption is introduced.

Fresh verification: Tripling, producer controls, six-theorem axiom readback, and reviewer controls all exit 0. All 63 manifest/source bindings match. Named axioms: propext, Classical.choice, Quot.sound.

Reviewer controls exercise characteristic 3 repeated support, characteristic 5 zero derivatives, and characteristic 2 cancellation. Four earlier reviewer fixture failures (imports / finite-field simplification) remain recorded, together with two manifest-reader preparation errors.

Boundary: retained field-expression source fidelity, not UInt64/compiler/counter behavior or divisor-class addition. The classifier conclusion is positiveCoincidence; the repeated-support premise and source order identify the tripling call. Existing dependency binaries were reused, without an independent kernel-binary rechecker.


Independence: reviewer did not author tripling, but authored its positive-distinct dependency and reviewed earlier dependencies. This is disclosed in REVIEW.md. No producer edits or scientific runs. Cost ratios remain null.
