Weighted 2+2 cross-scaling boundary

`projective-law-cross-scale22/v1`. The source checker compares eight power intermediates, eight cross-scaled inputs, and seven composed coefficient expressions from Rust and Lean as expanded integer polynomials. All 23 match. Multiplication-to-addition mutations on both sides and a composed-coefficient subtraction mutation are rejected.

Input	Common Z power	Common W power	Equal
q1c	2	0	yes
q2c	2	0	yes
r1c	4	0	yes
r2c	4	0	yes
s1c	3	1	yes
s2c	3	1	yes
t1c	5	1	yes
t2c	5	1	yes

The Lean theorem proves these common weights from the weighted numerator equations over a commutative ring. It does not establish the returned Jacobian class, exceptional branches, or a cost change. The accompanying CSV and JSON retain all 23 rows and all polynomial terms.
