N83 planted four-summand control: bounded outcome

The exact K = 16,627 stored signed-Frobenius base and five compiled worker sources passed the frozen hash checks. The native release worker ran in a one-CPU, 4 GiB, zero-swap container. Its pinned positive arm reached the 1,800-second wall cap and exited 124 without OOM. Cgroup memory peaked at 2,660,335,616 bytes. No worker JSON or phase receipt was written.

Status: `UNKNOWN_wall_cap`. The stopped phase, SAT conflicts, candidate models, group relation and rank are unknown. The unpinned arm was not attempted because the positive-control prerequisite was unverified. This is a censored experiment, not a natural relation-yield estimate or a complete IC cost. The next experiment records phase boundaries and fixes the complete planted x-coordinate chain before SAT search.
