# Independent target-score review

Publication: `125c631e4005785e344167d8f699b4bf23415fe6`.

Five producer fixture groups reproduced the published JSON exactly in a fresh offline locked native build. Five reviewer fixture groups passed; three deliberately inconsistent cases reached and caught the native inconsistent-relation assertion. Full native source and insertion-policy source match publication byte-for-byte.

**Zero score and constants.** A zero-score edge can create an anchor useful to a later scalar-returning edge. The score omits the constant coefficient: equal scores cannot distinguish a consistent zero equation from contradiction. Reviewer controls test opposite signs and positive/negative equal signs on an anchored same-root component. Consistent cases return no scalar; changed constants trigger the native assertion. Separate anchored nonzero-coefficient cases return 6 over the field of order 7.

**Actual insertion policy.** At `three_leads_followup.rs:347-356`, rank mode computes priority from score, then inserts the accepted unseen split edge regardless of score. The priority subsequently affects walk-state selection. These controls identify no zero-score insertion-filter defect.

**Instrumented call.** The first producer score call records 6 scalar additions, 2 find visits, 0 scalar multiplications and 0 inversions. Constructor and edge insertion are excluded. These are call-specific instrumentation deltas, not comparative measurements.

**Evidence.** Two native builds and two fixed fixture executions exited 0. The producer JSON comparison is empty. Three panic messages in reviewer stderr are expected caught assertions, not failed fixtures. Inputs were rehashed after execution. Group counts are not assertion counts. See `REVIEW.md`, `status.json`, `receipts.json`, native stdout/stderr and SHA256 manifest.

**Review boundaries.** Review follows publication and a saved source-first plan; the reviewer has prior familiarity with this source and does not claim blindness. This is source inspection and fixed F7 controls, not a universal Lean theorem. Consistent input relations remain a premise for interpreting a returned scalar as the intended target. Arbitrary forest termination, all-size word bounds and policy optimality are outside these checks. No cohort, curve generation, timing, cloud execution or repository edits occurred.
