Independent V3 native evidence review

Read-only evidence review

5 November 2026

Result: failed-attempt evidence is consistent. Source `79588ee0ee62`; archive `a51006010dd6`. No reviewer rerun.

Checked progress. Nonbranch compiled with exit zero. IndependentControls exited one, stopping the sequence after two of four calls. Readback and ExpectedFailure did not run: the thirty named axiom checks and intended negative rejection are not established. Complete machine review remains false.

Failure. Diagnostics show an invalid simplification theorem, polynomial and Bezout normalization goals, an unknown tactic, and an additive-valuation versus multiplicative-hom API mismatch. They identify control proof-script failures, not mathematical counterexamples by themselves.

Custody. Full pre/post dictionaries are byte-identical: 16,736 entries and 3,111,892,318 bytes each. Runtime pins and four copied source texts match. All three terminal owners are evidenced; compiler service retains matching failed invocation, MainPID zero and empty cgroup. Both Lean children were reaped. Full post custody completed after failure.

Time. Native pre 152.628, compiler 303.263, post 125.004 seconds; outer 582.324 seconds versus 2,400 ceiling. These are wall durations. Earlier 1,200 charge and full attempt reservation remain distinct; no additional attempt is authorized here.

Archive. Fifty-five manifest entries and all 46 raw bindings match. Remote archive identity is recorded by producer download/readback; that download was not independently repeated. The reviewer compared saved dictionaries, without rereading 3.1 GB of dependencies. Shared-cache transient changes remain a trust limit.

Next construction. Correct independent control source. Any future execution requires a new approved attempt protocol; no source edits, compilation or retry occurred in this review.
