Correction 2026-10-20 (validation sweep B, verdict 110.1: contradicted). The N83 18.528 rho/IC ratio below compares against rho with an empty table on one L0 target. It is superseded and is not an improvement; precomputed rho wins every N83 matched pair (benchmarks/20261016-n83-precomputed-rho-control). The within-IC K1798 vs K1500 result stands.

N83 packed-root capacity and prefix-base result

K1798 dense · 298,468 usable points · 1,798 folded columns · 8 GiB allocated root slots

K1798 dense is the lowest-mean-probe completed prefix base in the frozen 64-point comparison: 169,069.8125 probes per target, versus 300,021.90625 for K1500 dense. The paired mean difference is 130,952.09375 probes, 95% bootstrap interval [52,057.703125, 209,990.828125]. Complete archived-base, four-point relation and scalar replay passed for all 256 target rows in the four completed arms.

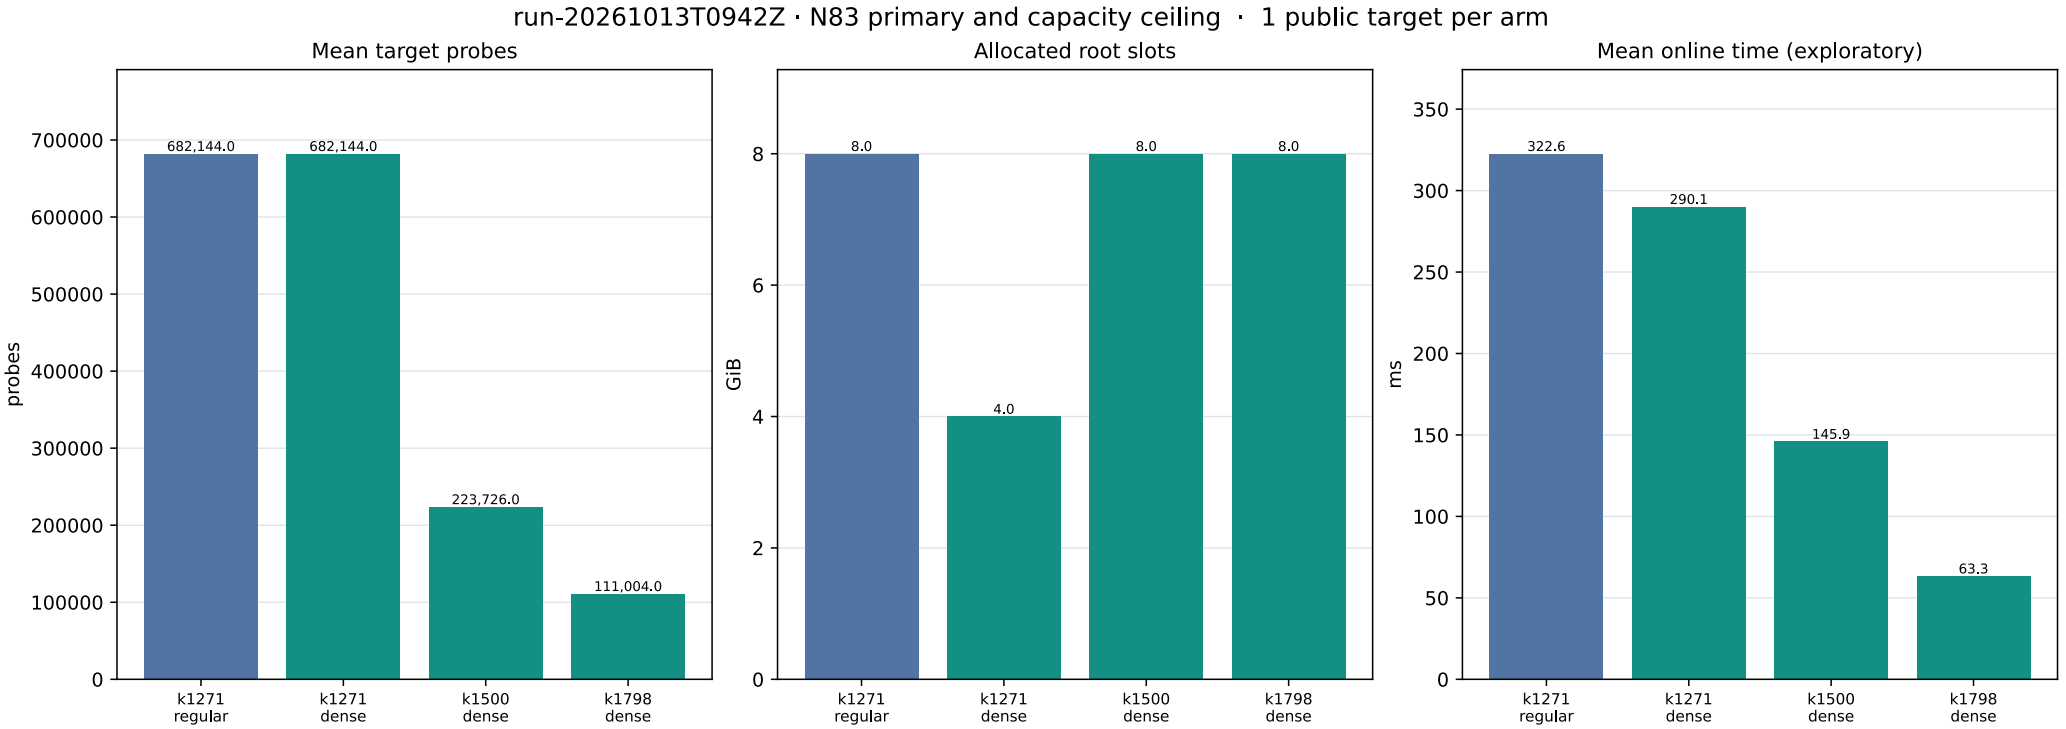

Figure 1: Single public target: exact probes, root-table allocation, and exploratory online time. Source run: run-20261013T0942Z.

The same public target was solved in 63.324125 ms online by K1798 dense and 1,173.29325 ms online by the selected strong-rho control, giving an exploratory rho/IC ratio of 18.528377 on the shared Apple M4 Pro host. Both recovered scalar 2927171373054142 and passed independent generic-curve replay. IC preparation was 319.165 s setup, 19.825 s rank and 0.014 s final matrix algebra, outside its target-online timer. K1500 regular reached exit 124 at the 900 s cap in both primary and panel runs.

The exact curve is degree-83 Koblitz $a = b = 1$ over polynomial $z^{83} + z^7 + z^4 + z^2 + 1$, subgroup order 8,569,786,107,849,059. All IC arms use rank seed 29, 12 rank threads, one target thread and the same producer binary. K1271 regular/dense first witnesses matched on all 64 points; dense mode reduced its allocated packed slots from 8 GiB to 4 GiB. Six Lean 4 current-capacity theorems built without axioms; two conditional 75%-load theorems also built, one using standard `propext`. The Rust-loop bridge remains partial. The proposed 75% rule is not a measured arm.

Evidence: `analysis_primary.json`, `analysis_panel.json`, `runs/`, `PROTOCOL.md`, `PROOF_MAP.md`, and the two run reports. CPU isolation was not established on the shared host; controlled speedup remains null.

Frozen panel and proof

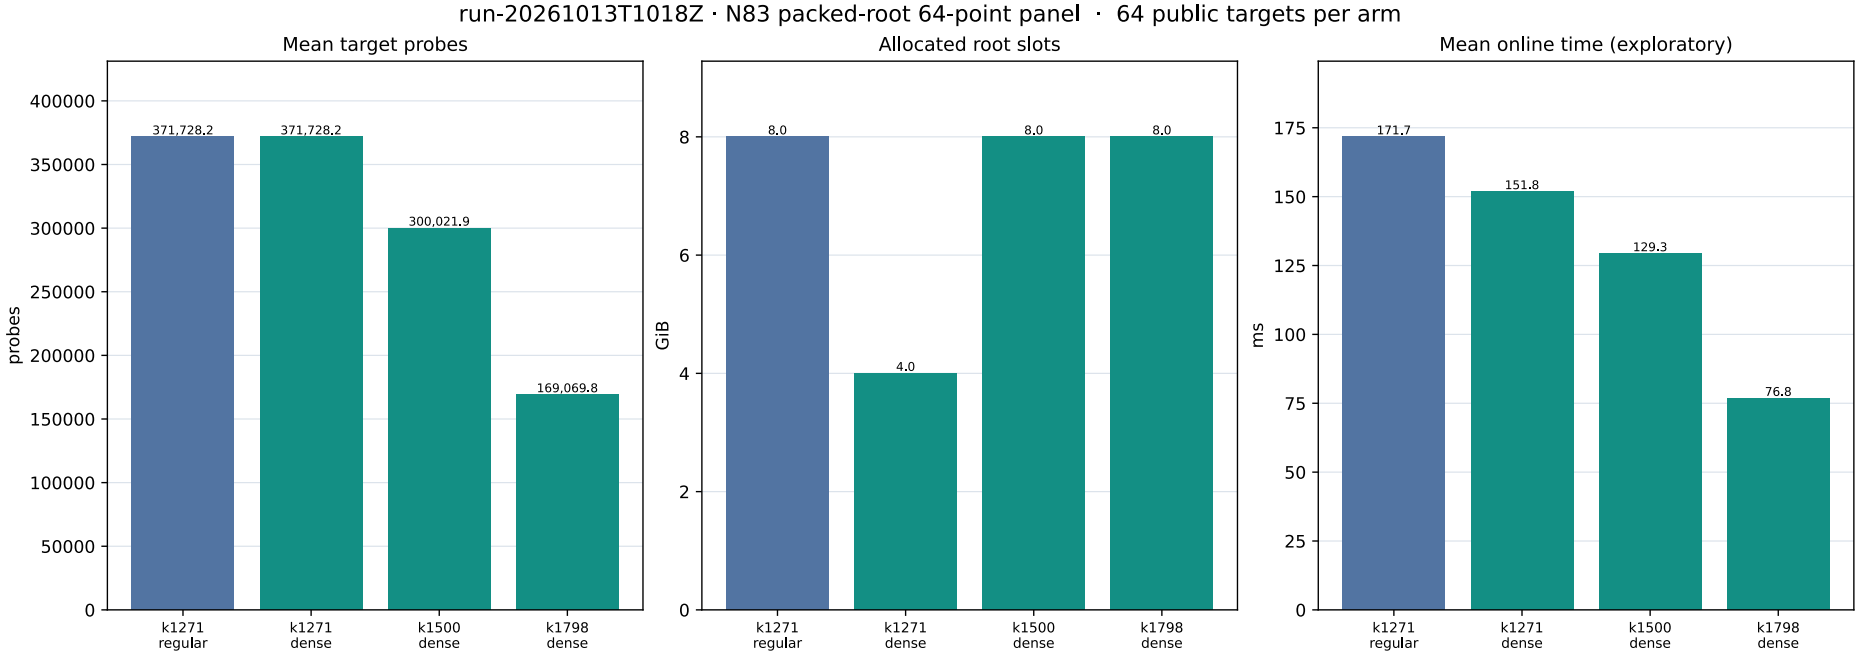

Figure 2: Mean target probes, allocated slots and exploratory online time on the identical 64 public points. Source run: run-20261013T1018Z.

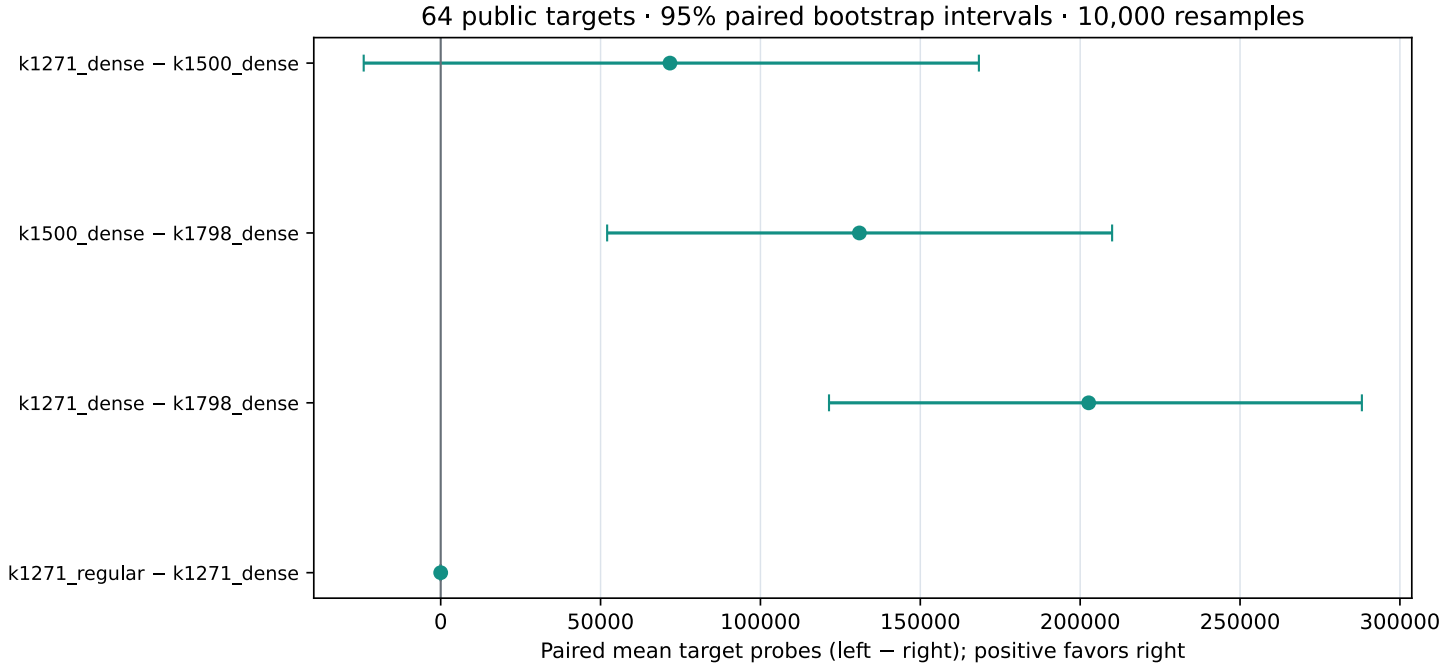

Figure 3: Paired mean-probe differences, left minus right, with 10,000-resample 95% bootstrap intervals. Positive favors the right-hand arm.
