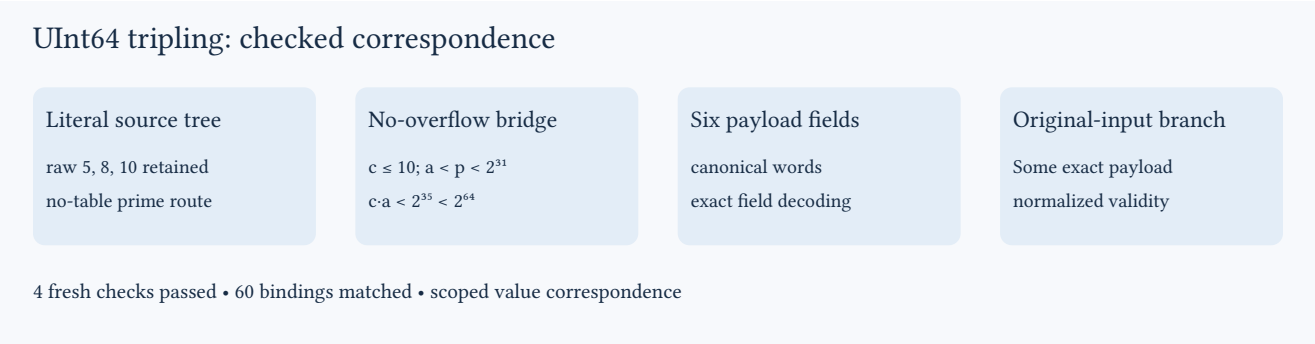
Independent UInt64 tripling review

Result: validated at the retained no-table prime-field value scope.

The literal source tree, six canonical output words and exact field decoding were checked. Raw literals 5, 8 and 10 are retained, including small primes 5 and 7; the proof establishes modular reduction equivalence with an explicit no-overflow bound.

For $c \le 10$ and canonical $a < p < 2^{31}$, $c \cdot a < 2^{35} < 2^{64}$. Canonical dynamic products separately satisfy $a \cdot b < 2^{62}$. This does not justify table indexing: Field.n=1 and tables=None are explicit source-route conditions.

The branch theorem derives Some of the exact payload, nonzero weights and normalized output validity from original valid inputs and actual branch guards. No output-validity or nonzero-derivative premise is introduced. Other dispatcher branches remain outside the scoped conditional.

Fresh module, producer controls, four-theorem axiom readback and reviewer controls all exit 0. All 60 source/manifest bindings match. Reviewer controls include a full p=7 zero-derivative branch, small-prime literals, maximum-envelope product and a noncanonical input rejection.


Reviewer did not author the word candidate but reviewed the tripling field dependency and authored an imported positive-distinct dependency. Existing pinned dependency binaries were reused. No compiler, counter, table-backend, divisor-class or whole-walk claim is inferred; no scientific runs occurred. Cost ratios remain null.
