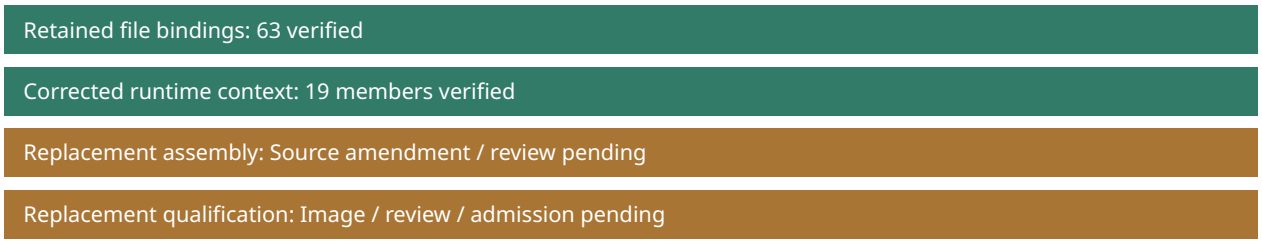
Replacement runtime input contract

Read-only verification, 2 November 2026. Sixty-three retained files match their bound SHA256 digests. The staged context matches its complete 19-member inventory and modes; the retained qualification fixture closure matches all 32 manifest members. These counts overlap and must not be added together.



Read-only input checks. Counts overlap. No new assembly, qualification or scientific result.

The joined inputs include the retained ecbench binary and build receipt, materialized-source manifest, build-info bytes, smoke fixture, runtime member ledger, gate binary and gate-control receipts, prior gate review, qualifier source, HEAD parser and Docker/curl clients. The binary remains the retained static-musl build from revision 3c592af; this packet does not rebuild it or claim the newer observer code is present in that binary.

Fresh bounded Docker metadata queries confirm the exact base image is present as linux/amd64 with empty OnBuild. The local daemon reports no containers. No image payload, build, container creation/start, cloud query or scientific execution occurred. The observations are local and timestamped; they do not establish EKS job idleness or future daemon state.

The replacement qualification binding preserves the retained source inputs but explicitly sets admitted=false, replacement image=null and prospective review=null. The proposed assembly is one runtime-only COPY build with no pull/network, at most 600 seconds including 60 seconds reconciliation reserve and a 240-second build-client limit. The proposed qualifier retains its 300-second bound, 30-second cleanup reserve, one active container, 512 MiB, one PID and strict empty writable-layer diff. These proposed limits are not a renewed execution allowance.

The assembler still needs an exact reviewed amendment for the staged corrected context and a new owner/tag. A new image identity and independent qualifier-binding review must follow successful admitted assembly. Mounted-root metadata and placeholder metadata remain runtime observations, not inferred layer facts. The historical Q1 failure and old image identities remain unchanged. Independent reviewer agents currently report usage-limit errors.

The read-only checker passed all input joins. Four helper controls passed: exact bytes accepted; wrong digest, symlink and duplicate JSON key rejected. Initial 60-file readback is retained beside the expanded 63-file readback. These checks establish byte joins and stated local conditions, not execution admission or mathematical source fidelity. The 1,260-target scope and 25,200-worker-second planning ceiling ending 2026-11-03 06:00 UTC remain unchanged.
