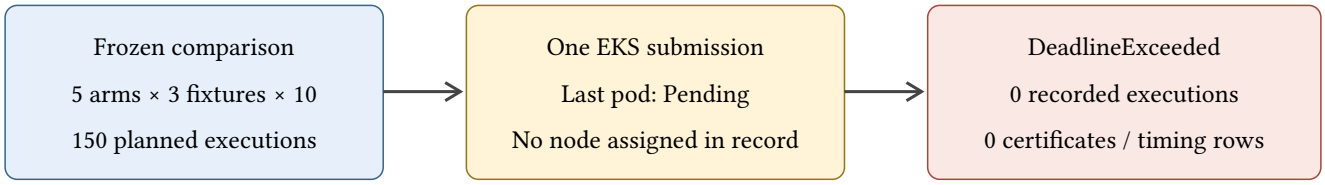
CPU Curve reciprocal candidate: scheduling failure

Observations only; no algorithm measurement, speedup or hypothesis promotion. Job `hashed-ecdl-cpu-round17-20261030`, October 30, 2026 UTC.

The candidate reuses the existing reciprocal field-reduction context in Curve membership checks, the curve equation and checked affine arithmetic. Modular sums use bounded additions; larger fields retain wide remainders. The inline context adds two u64 values (16 bytes), with setup charged. Both complete certificate replays remain. The previous inverse cache remains.

Candidate source: `23ff0e6bda635d428417024a8ab17e233f7d9af4`. Reference: `5d7dcb67616c`; original baseline: `2bd4588fba60`. Software validation:35 release tests, strict all-target Clippy and formatting pass. Independent tests use u128 remainders and Fermat inversion, bypassing both production kernels. This does not establish performance.



hashed-ecdl-cpu-round17-20261030 · 300 s scheduling deadline, not algorithm time

Protocol-planned executions	150 (135 measured + 15 warmups)
EKS submissions	1
Recorded algorithm executions	0
Retained certificates / timing rows	0 / 0
Retry submissions	0
Final job state	Failed: DeadlineExceeded

The job was created at16:05:42Z and reached its300-second deadline at16:10:42Z; Kubernetes recorded Failed at16:10:43Z. Last observed pod was unschedulable, with no node assignment: one node violated pod anti-affinity, two did not match affinity/selector, and two had untolerated taints. The terminal status has no retained pod. This is an infrastructure outcome, not a solver timeout or evidence of a slow algorithm. No measured CPU model or algorithm time exists.

Expected results-object HEAD returned404. No native analyzer ran and no timing or certificate archive was returned. The frozen input bundle and source/binary identities are retained. No synthetic executions fill the missing cells. The empty export records zero observed executions; the frozen protocol still plans150. The completeness checker reports eight findings: missing arms, missing planned rows, five per-arm instance shortfalls and unperformed masked analysis. The export is an incomplete failure record, not a passing panel.

The first verifier-region receipt accidentally hashed an empty slice. Before measurement submission, the endpoint was corrected and the script required a nonempty region containing verify. The actual3033-byte region is identical to the preceding source. This correction changed metadata only and is preserved in repository history. Remote branch advances were merged before publication; all frozen candidate source hashes still matched after reconciliation.

Protocol: `d5f974403ab76e04927ff53b75cf89e6fcd42b9011921b9a3c88a8a2022fa084`. Job UID: `008f64ff-e845-4bed-94c4-f475f6788e04`. Raw status, input receipt and failed export: `round17/`. Raw evidence was pushed as `90d1adb048be` before this report.

The further10x goal remains unproven. Round16 timings apply only to the prior candidate, not this one. Candidate end-to-end timing, strict isolation, independent scientific review, external/rho comparisons and larger-scale CPU recovery remain open. No automatic retry or replacement job was launched.
