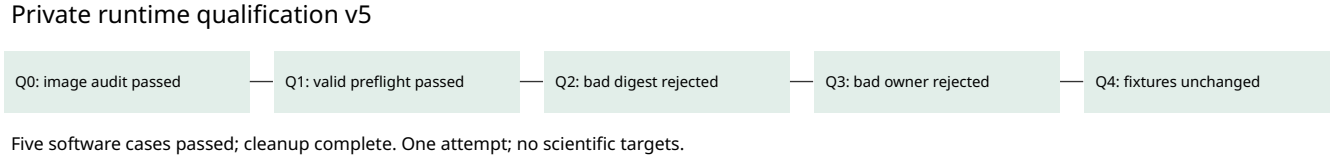
Private runtime qualification v5: Q0–Q4 passed

The single v5 attempt completed all five software qualification cases. The outer launcher returned 0 after 39.186950947 seconds; the inner qualifier recorded 6.383614638 seconds and cleanup_complete=true. The service journal records 13.828 CPU seconds. These intervals cover different boundaries and are not added together or used as a performance comparison.



Q0 checked the exact image, configuration, static executable identities, runtime members and metadata custody. Q1 passed the diagnostic-preflight positive control with expected exit 0. Q2 passed rejection of the wrong request digest with expected exit 2 and the expected message. Q3 passed rejection of the wrong owner-configuration digest with expected exit 125 and the expected message. Q4 checked unchanged fixture snapshots and gate bytes. A negative control passes when it rejects the deliberately invalid input. The standardized cases.csv binds these meanings to the published qualifier and native receipt.

For Q1–Q3, the held PID1 gate recorded UID/GID 1000, pids.max=1 and pids.current=1 after container startup and before the tested program executed. Three corresponding host-ancestry records bind exact container IDs, nonces, process start ticks and cgroup device/inode inside the owned service. This is not an observation before container startup or a claim of continuous enforcement.

The worker records qualified_stopped, mounts closed, shim state resolved and endpoint_live=false. Captured unit state is not-found/inactive/dead with MainPID 0; cgroup state is empty/absent and associated loop devices are empty. Read-only debugfs receipt extraction left recorded disk metadata unchanged. Disk digest f38930c6e068ab0e18cae8b6881bbb3a3087ad5b4ddb1775a4ec53785d214a95 is inherited from the worker; the report producer did not rehash the full disk.

One 300-second service with two CPUs, 2 GiB memory and the retained 4 GiB filesystem was admitted. Conservative debit remains 600 worker seconds and USD 1 for this attempt, regardless of its shorter elapsed observation. Campaign cumulative debit is 3000 seconds, with 22200 remaining through 2026-11-04T06:00UTC. Dollar reservations total USD 59, including the existing shared reserve; actual dollars for this attempt are unmeasured. Earlier failures and their debits remain preserved; there was no automatic retry.

The prelaunch publication receipt binds the exact source/admission files to GitHub commit f3e799286da55d5fa88a375d45607ff4a6519688. The report's JSON binds the raw evidence bytes. Independent postreview is pending and will be recorded separately. This was software qualification and diagnostic-preflight execution; no scientific target or matched cohort was run.
