One issued Lean binding stops inside its signature

Result. The independent native Lean official-parser audit resolves62 named bindings in65 source plans added to this stacked feature:61 complete written signatures, one truncated issued binding, zero unresolved. Snapshot1f0eba8e31c5d77626b13c1ab932757056366739. Three native/catalog-only plans remain explicitly outside the theorem count. These are surface-header observations, not proofs of theorem truth or all historical claims. [pcc:unverified]

Bounded native audit	62 named bindings in 65 immutable source plans 61 complete written headers; 1 issued prefix; 0 unresolved
Concrete BK receipt	Stored header176chars ends inside geomCurve (L:=L) Official full written header913chars; original37-proof gate retained
Evidence boundary	Lean: genuine controls + delimiter-model noninjectivity Native count is procedural; no false theorem/signed status inferred

Affected receipt. PCC-20261110-99983d, BKActualCertificateAudit.bk_actual_case_audit_certificate, stores176characters ending at geomCurve (L, before a legal named-argument assignment. Stored hash f56bb53d… differs from full written-header913characters/hash1f432993…. The existing actual-object source, source pins and whole37-declaration Lean gate are preserved; the observation does not refute the BK theorem. A complete versioned wrapper is the next repair, with no old-claim/ledger/source rewrite. [pcc:unverified]

Independent parsing and controls. The comparator uses official Lean4.35 command grammar, byte ranges, actual compiler parser context and qualified source-namespace selection; source and stored hashes are checked. Seven genuine declarations cover bars, named arguments, default proofs, inline by, comments, strings and a complete positive control. Actual frozen-extractor output is separately captured. Native comparison controls produce4prefix/1complete/2explicitunsupported normalization cases, expected exit1. No unsupported case is counted as a pass. [pcc:unverified]

Failed pass retained. The first corpus pass gives58complete/1prefix/3unsupported. Source-declared Matrix notation context and a same-short-name namespace ambiguity are diagnosed; the second pass uses identical immutable inputs and finishes61/1/0. A public-equivalent-tree replay reproduces61/1/0. All63 candidate source hashes/pins match. The final bounded headers contain no unsupported comment/string policy cases. [pcc:unverified]

What Lean proves. Kernel-checked semantic controls and a transparent List-Char delimiter model: concrete unequal strings have equal prefixes for three delimiter constants, so each model function is not injective. The model is not a formal refinement of Python regex, native auditor or SHA256. Native counts remain procedural evidence. Complete written headers also do not bind ambient variable telescopes, all definitions/dependencies or fully elaborated kernel types; canonical semantic binding remains a separate contract. [pcc:unverified]

Provenance and checks. Whole model/control gate 8/0 failures/0 trusted native exceptions; 419 build/runtime/input/provenance files preserved losslessly in 140 objects, including failed controls/first pass and final gate. Long-dictionary XZ raw-tree archive is58788bytes, below65536; full-signature index/raw written headers and immutable Git restore recipe retained. Frozen verifier SHA5e1a9703… unchanged. Lean4.35.0/Mathlib56a00585…, standard foundations/default settings. Signed standing unverified. No holes/custom axioms/native proof evaluation/unsafe initializer call/flags/limits/waivers/cryptographic experiment/spend/upload. Original fourteen-item gaps remain. [pcc:unverified]
