N83 D18: independent construction-policy audit

Run 2026-10-24 06:40:42–06:42:50 UTC · revision 5e2dc2583

The native freezer and archive auditor now independently enforce the actual construction container's successful exit, 4 GiB memory, zero swap, one CPU, no network, read-only root, process/capability limits, pinned image and exact capped command. The preceding version checked the receipt hash and relied on the shell preparer to enforce the resource policy. The frozen policy is unchanged.

Gate	Observed result
Full release library	4,478 passed; zero failed; 119 ignored
Eight affected examples	29 passed; zero failed
Updated native auditor	Release build exit 0

One new test independently changes memory, swap, CPU, write access, network, running state, OOM state and exit status. Each altered receipt is rejected; an empty container list is also rejected.

Source: `n83_d18_shared_card_audit.rs`, revision `5e2dc2583`. This diagram describes validation. It supplies no solver timing or natural-query result.

Host: shared Apple M4 Pro / arm64; Rust 1.98.0 selected explicitly. The native busy lock serializes work; it does not qualify timing. The worker, general-field replayer and construction executable are unchanged. The six-model reconstruction remains in the earlier versioned run. This run performs no SAT query.

The 17-file validation-v4 archive was extracted, every file hash checked and repacked identically. SHA-256: aca521b35b0523e0e3732f1dcd2b2cbcec29c58e895717740bb40070f63ba7d6.

The Linux construction/card and current-head PR CI remain open gates. Natural useful rank, complete cold/reused IC cost and matched rho remain open. The queued worker source is `4e1d311d8`; the updated auditor independently checks that source's construction and worker receipts. Canonical runtime charts and benchmark entries stay unchanged because this run adds no timing comparison.
