N83 D18: Linux validation and gated continuation

2026-10-24 UTC · native worker revision 4e1d311d8 · shared x86-64 host, L0

The Linux full-library gate began at 06:50:23 UTC using Rust 1.99.1 and exited 101: **4,473 passed, 15 failed, 119 ignored**. No affected-example, release-worker, bounded-construction or solver-card stage followed it.

Nine failures report runtime fixtures absent from the sparse checkout. The exact committed evidence paths, SOURCE42 rows and chain-set fixtures are now materialized; source status remains clean. Six solver assertions also failed: two explicitly report timeouts, three zero qualifying trials and one a missing planted solution. The earlier description of all six as confirmed deadline failures was too broad. A full serial rerun will distinguish deadline/contention effects from other causes. No test or existing limit has been weakened.

An unrelated benchmark container was active when the failure was inspected. The shared lock therefore does not establish an uncontended timing interval.

Source: validation-v5, frozen PROTOCOL.md and admission scripts. Status at 2026-10-24 07:24 UTC. This diagram contains no timing comparison.

The replacement pipeline was queued at 07:24:42 UTC, PID 1841122, with a four-hour admission limit. Native notification integration is checked first; then the full library runs with one test thread, followed by the affected examples, native builds and the original six-model bounded construction. The actual host card is independently checked locally and committed/pushed before admission. The benchmark lock is released during publication and reacquired before the unchanged frozen schedule starts. Invalid controls stop natural work; completed or failed receipts are collected automatically.

The local Apple arm64 validation at 07:17:32–07:19:57 UTC again passed all 4,478 library tests and 29 affected-example tests (119 library tests ignored). Workflow/shell checks and one notification-state test pass. Linux file-event and timeout integration remain queued. Platform-specific test populations differ; these counts are not a speed comparison.

The 39-file validation-v5 archive preserves the failed Linux run, passing local run, sources and continuation commands. Every file hash was checked after extraction, and an identical archive was repacked. SHA-256: 0307e0c981f459e4d6b42ffbefa51806f337b670519b8cbbc1f2b580ecb67f56.

The host card, 22 controls, 22 independent replays and 18 natural queries remain pending in this record. Final independent audit, result reports and PR merge remain gates. Useful rank, complete cold/reused cost, matched rho and best-base selection stay open. No new solver timing is reported; canonical runtime charts and benchmark rows are unchanged.
