Independent duplicate-adapter review

Independent review · root

Rendering: original producer, kummer_transitions

32 artifact hashes 18 preexecution bindings	Fresh offline replay: exit 0 8 controls · identical parsed output	2 planted candidates verified 1 edge / 0 cycles per case

Scope: isolated helper correctness. No new trajectory or complete cost ratio.

Independent reviewer: root. Renderer and original producer: kummer_transitions. Findings below are root's; rendering adds no review or replay.

Root inspected the helper, fixture, native scalar-order checks and graph forwarding, verified 32 producer hashes and 18 preexecution bindings, and ran one fresh offline replay with a separate target cache. The native exit was zero and parsed output matched the producer exactly: all eight frozen controls passed.

Both scalar labels are negated when the signed divisor is canonicalized. The first graph edge still receives its original signed divisor and original labels; a duplicate is evaluated before graph suppression. Prime r, nonidentity G and rG=0 establish exact order for the stated valid group domain. rQ=0 alone does not establish Q membership in that subgroup, and the helper correctly documents membership and D=aG+bQ as caller obligations. Incoming divisor validity and collector eligibility are also external obligations; this is not a hostile-input validator.

The informative labels are deliberately constructed from the public known scalar 31124 on p=739,r=34147. Both accepted candidates are verified by native scalar multiplication. The changed-target control deliberately violates the initial label invariant and is rejected at candidate verification; it is not evidence that first-edge insertion validates arbitrary labels. The graph retains one edge and zero cycles throughout every case.

Initialization, reference-label checking, graph processing, scalar arithmetic and candidate-verification fields are reported separately. Hashing, memory, comparison work and fixture construction are not fully priced. No natural collision rate, trajectory yield, end-to-end performance or complete-cost ratio is established. No blocking discrepancy was found at this isolated correctness scope.
