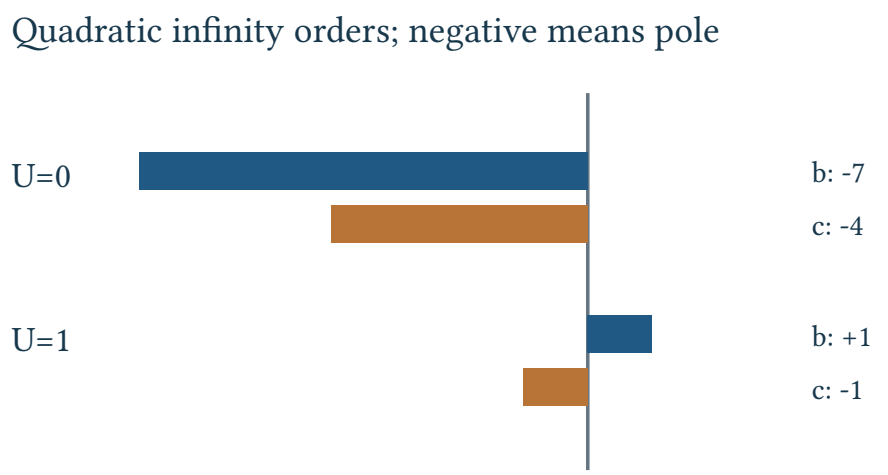
R77: the missing infinity zero of b

The quadratic source equation becomes $U^2 + U = t + t^3$ at $t = \frac{1}{z}$, with two etale infinity places $U = 0, 1$. Exact native quotient checks give $N(B) = t^5$ and $N(B + t^3) = t^3(1 + t)^3$ for $B = 1 + (1 + t)U$. Three pinned Lean polynomial and degree theorems compiled and passed an axiom audit with zero failing and zero trusted.



Each quadratic place contributes weighted degree 16 in the full source.

At $U = 0$, both factors are units; the norms force orders five and three at $U = 1$. Since $b = t^{-}7B(B + t^3)$ and $c = t^{-}4(B + t^3)$, the proper pole degrees in the degree-32 source are 112 for b and 80 for c. The second infinity place also contributes a zero divisor of degree 16 for b, correcting R76's inference from finite zeros alone. Individual degree-32 infinity branches remain to be split.

One native and one Lean run passed. Eleven historical source-byte pins and five donor hashes match. The additive R76 erratum preserves its sealed original evidence.
