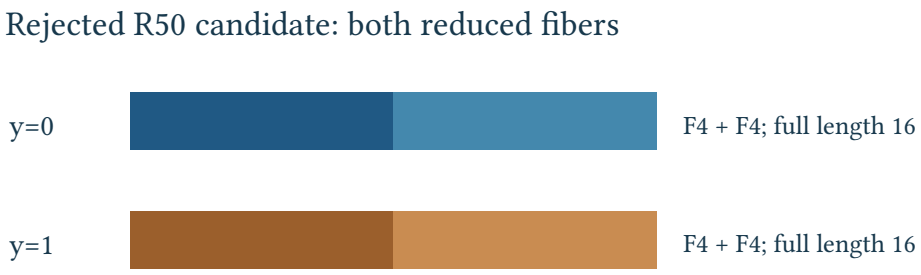
R80: reduced fibers of the rejected R50 normalization candidate

Both $u = 0$ candidate quotients have dimension 16 over F2. On each component the radical quotient has dimension 4 and exactly two degree-2 prime quotients. Their degree sum is exhaustive: $2 + 2 = 4$ on each component.



Each colored block is one candidate degree-2 prime quotient.

The reduced dimension is 4 at each place; nilpotent length accounts for the rest.

Normality and source-field compatibility remain unproved.

The two serial frozen programs passed exit, exact-marker, error, source-byte, and donor checks. These are candidate-algebra factors. The R50 candidate failed its earlier coefficient-descent gate, and neither normality nor source-field compatibility is certified. The next check must compare the four proposed factors with an independent local integral closure.
