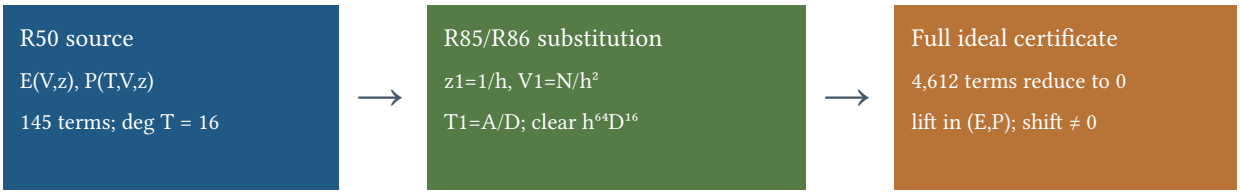
R87: the full relative equation under diamond pullback

The retained inverse-base source algebra has the quadratic equation `E(V,z)` and a monic degree-16 equation `P(T,V,z)`, with `T=lambda`. The R85/R86 diamond substitution gives `z1=1/h`, `V1=N/h²`, and `T1=A/D`. Multiplying by `h⁶⁴D¹⁶` clears every denominator of the 145 source monomials.

R87: complete degree-16 source equation under diamond pullback



Next: explicit inverse and regularity lifts for all 32 normalized RR generators.

The frozen Singular attempt built the complete 4,612-term pullback, reduced it to zero modulo `(E,P)`, and checked a full two-generator ideal lift. A shifted lambda update produced a nonzero remainder. Its source bytes and four donors are hash-pinned. Lean proves the characteristic-two shift identities for the powers used by that negative control; the large ideal lift remains a native certificate.

Next derive the inverse upper-field formula, then transport every generator of the accepted rank-32 RR PID basis with complete module lifts in both directions. That will test regularity at the chart boundaries.
