# Permit fixture startup source review

1. Capture timezone from the imported datetime module
2. Bind class-local datetime to the fake DateTime class
3. Run the same 24 fixed qualification cases

Source review passed scoped.

The one-line assignment reversal fixes class-local datetime shadowing. Actual worker/launcher bytes, source pins and all24 case bodies/order remain unchanged. Remaining startup bindings and extracted-function globals were inspected without execution.

Initial attempt: exit1; elapsed0.06454660795861855s; full60seconds charged. No durable qualification result. Fourteen worker calls precede the failed class definition; source order and traceback imply they returned, but no per-case receipt survives. The complete24-case qualification did not finish.

The reviewer previously reviewed the v4 fixture and missed this class-scope defect, but did not author the successor correction.

Next step: publish the exact corrected fixture and coordinator-release one separate60-second qualification. Preserve50s internal alarm,55s outer timeout plus5s kill,512MiB address limit and1MiB file limit.

No qualification, compiler or native payload execution by reviewer.

Evidence: review.json, source-bindings.json, REPORT.md and manifest.json.
