Common 2+2 coprime-support uniqueness

`projective-law-common22-uniqueness/v1`. A pinned Lean check first proves an explicit Bezout identity: the common-branch determinant B is a linear combination of the two quadratic supports. Thus $B \neq 0$ makes them coprime. Given interpolation and valid-input curve congruences, Lean proves that each support divides $H = E - B^2F$. If $\deg H < \deg(u_1u_2)$, then $H = 0$ and $E = B^2F$. These are conditional polynomial statements.

Obligation	Recorded status
Support coprimeness from $B \neq 0$	Kernel checked, conditional
First and second curve residues	Kernel checked, conditional
Degree bound from source	Open source link
Coprime low-degree implication	Kernel checked, conditional
Divisor-class conclusion	Open geometry

The CSV and JSON enumerate the obligations separately. This is a polynomial equation bridge, not a universal group-law proof. No DLP run or price changed in this packet.
