Saved validation002: independent count extraction

27 October 2026. Under source 27018452d455be75b27167812cb0d8f11a2876d4, the separate C++ token scanner re-extracted all 210 cells from all 21 original packets. It reproduces all 40 cutoff envelopes and retains explicit extremum witnesses. Wrapper and validation status are zero. Wrong-count, missing-row and changed-status controls each exit 1 for the intended reason. No legacy execution was repeated and no additional historical sample was created.

validation002: four componentwise inequalities

Keeping prime239v1 under any monotone upper budget also keeps both omissions

Edges are the four verified pointwise inequalities of ten recorded counts, not isogenies or attack transfers. This diagnostic was explicitly declared after primary results. Each omission is no larger on any coordinate than each shown published control. Exact vectors are in the checked native table; no normalized score or timing value was computed.

The independent verifier binary was fully downloaded and byte-verified before execution. Both saved extraction and negative cases use60seconds and768MiB. Shared local analysis earns no isolation tier; host/timing/RSS were not recorded or admitted. There is no random seed or performance reference arm. All source and raw-input rechecks pass. Raw archive runs/validation002/ preserves launch source, outputs, statuses and each negative case. Protocol, verification, witnesses, byte gate. This is separate native implementation checking by the author, not independent human research review.
