Item 17 — original n=23 solver cells

The existing native runner executed its original n=23 solver package: five declared cells, sixteen requested targets per cell, seed 20261012, 150-second cell time limit, node budget 1024, and the inherited engine. It exited 0 after a reported 1069.9 seconds, including the existing census/yield legs.

Two cyclotomic w1 cells timed out before emitting target records. Both matched ONB cells emitted all sixteen target records, but resolved no solving degree and lifted no decompositions. K0's ONB cell recorded four Boolean roots without a verified lift; K1's recorded none. The cyclotomic w2 encoding reported sixteen unsupported targets. WDSat was unavailable to this run because neither source nor binary environment variable was set; a checkout obtained later is not retrospectively credited.

Cell	Records	Outcome / degree
K0/w1/cyclotomic	0	150 s cell timeout; unresolved
K0/w1/onb_matched	16	Completed; D unresolved, reached 3
K1/w1/cyclotomic	0	150 s cell timeout; unresolved
K1/w1/onb_matched	16	Completed; D unresolved, reached 3
K0/w2/cyclotomic	0	16 unsupported; unmeasured

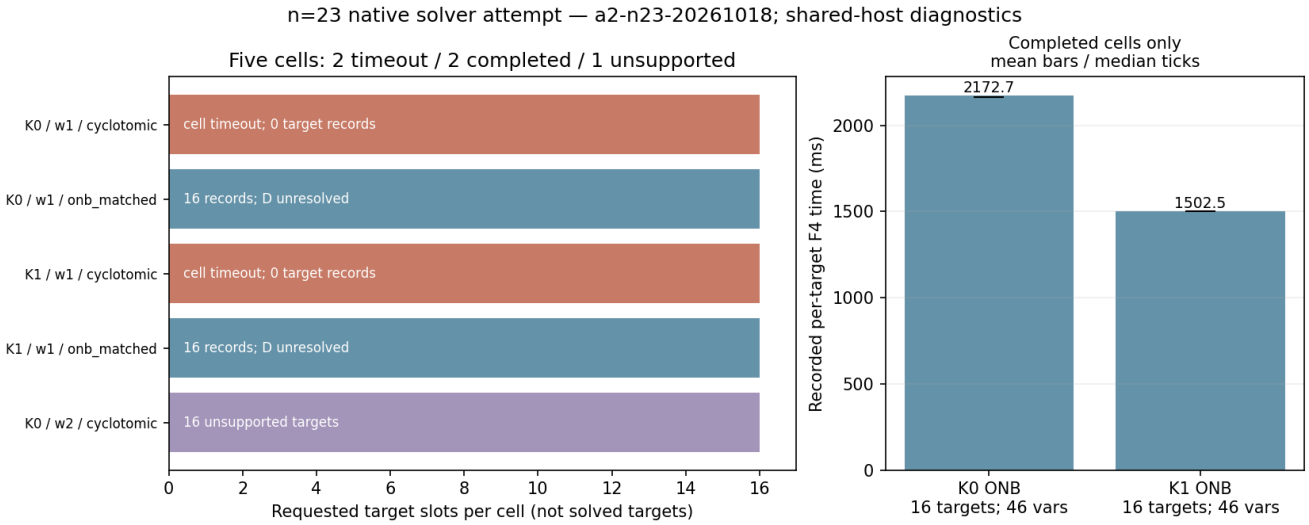

Figure: requested slots by cell status; the 32 completed records retain unresolved solving degree. Timed-out/unsupported cells have no per-target timing plotted. Only recorded means/medians appear; no uncertainty interval or speed ratio is inferred. Both completed inputs have 46 variables, 3,567 equations and input degree 3.

The reported wall times come from a shared host with concurrent builds and trials. They are not a speed comparison. Every failure and raw output is retained. The initial `/usr/bin/time` wrapper attempt exited 127 before any scientific work; the actual run used the shell's timing facility.

This does not establish a solving-degree crossover or a negative mathematical result. Exact argv/source and binary hashes, the build-repair patch, raw JSON, generated census/yield/solver table and stderr are adjacent. The separate `oracle_integration/` package supplies the new n=83 multiword construction and membership controls; it does not supply a complete n=83 F4 solve.

Provenance: manifest.json, a2_results_execution-20261018.json, input-sha256.txt, build-repairs.patch and original stdout/stderr remain unchanged. Exact argv, source base and working revision are in manifest.json. Seed 20261012; 16 requested targets/cell; 150-second cell timeout; node budget 1024. Initial wrapper failure exited 127 before scientific execution. No GPU, WDSat or solving-degree resolution is credited.
