Recovered-library development controls

27 October 2026. Frozen scope: human protocol, structured protocol, all 21 original group orders. Mathematical original-order proofs belong to the parent study; this report records software behavior.

Twelve development attempts were retained. Five strict-driver builds exposed original header-private declarations or nested comments; two unadmitted LP64 configurations timed out on generic fixture2; three ILP32 attempts failed on link-runtime, emulator executable mode or missing endian configuration. Two final explicit ILP32 builds pass13 generic fixtures through both methods (52 observations). Original source bodies were never patched. No historical order was executed in these development checks. Generic known-prime and composite fixtures exercise both legacy return values; they are not historical choices. Source audit names the required32bit unsigned-long/double word layout and the original configurator's DOUBLES_LOW_HIGH flag. All diagnostics and failed binaries remain in the preparation archive. The successful final build settings, source/binary hashes and controls are in PREPARED.json. No timing or speed comparison is reported.

References and complete source/binary hashes: source audit and prepared package. Original source licenses/notices are preserved. The local fallback and actual denied EKS routes are recorded prospectively; no paid resource, IAM broadening or unrelated default fixture was used.

Raw records are in preparation archive and final archive, with full member manifests and remote readback receipts. All 21 controls remain retained. No original historical caller, attack, security claim or measured DLP is established.
