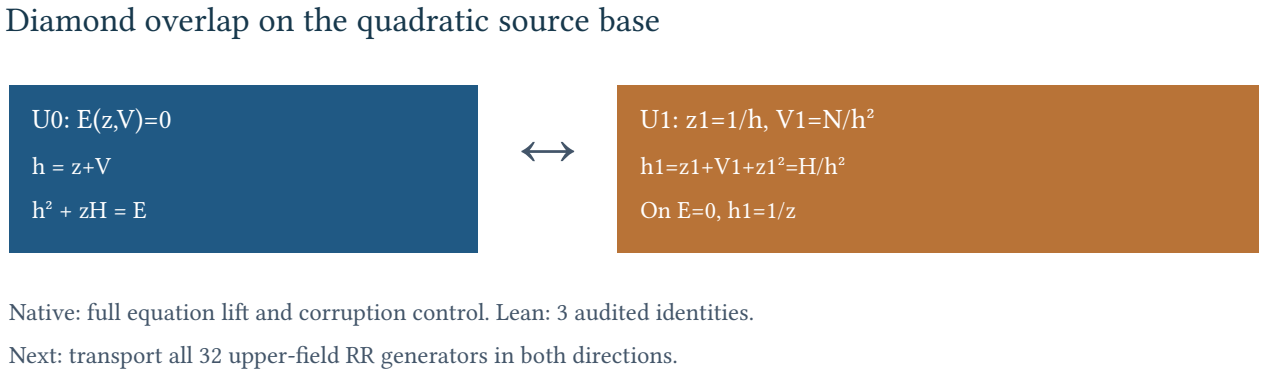
R85: exact quadratic-base diamond overlap

The frozen native program checks both principal-open polynomial products, a full lift of the denominator-cleared transformed source equation into (E), and rejection of a corrupted numerator. On the overlap where $E = 0$ and zh is invertible, these identities give $h_1 = \frac{1}{z}$ and the base-coordinate round trip.



The pinned Lean file compiled three characteristic-two identities and its axiom audit found zero failing and zero trusted theorems. This result fixes the base transition for the accepted R50 rank-32 RR algebra. The next check must transport all 32 upper-field generators and prove regularity in both directions.
