Final full V3 prospective source review

Independent operational source review

5 November 2026

Disposition: source adequate for final bounded full attempt. Published revision `79588ee0ee62`, freeze `dfde7d96367f`. No execution occurred.

Correction checked. The garbage-collection fallback requires current unit absence, empty invocation, terminal state and absent exact cgroup, together with trusted PID1/UID0 manager records matching captured invocation, unit and boot. Ordered start and success events are required; evidence is retained durably. Arbitrary empty identity, missing records, live replacement and remaining cgroup cannot pass. Journal queries remain bounded within the phase.

Preservation checked. Frozen hashes and exact Git bytes match. Four mathematical sources, thirty names and dependency/runtime bindings are unchanged. Native replay changes only workspace. Fresh full pre and post each check 16,736 files and 3,111,892,318 bytes. Completed old pre is not reused; old receipts and clocks remain unchanged.

Attack scope. Twelve producer mock cases were source-inspected, not independently run. The implementation orders journal timestamps rather than checking numerical phase windows; freshness relies on the newly captured manager invocation after absent-unit preflight and exclusive unit ownership. Filesystem calls are not hard realtime guarantees. Unknown termination must stop overlap.

Budget. Prior charges 300 + 900 = 1,200 seconds leave 45,600 of 46,800 before attempt 3 of 3. Phases 900/600/900, total 2,400 seconds; one CPU, 8 GiB, no retries; deadline 6 November 2026 04:00 UTC. The dollar-facts waiver changes no other bound.

Next step. Parent publication and admission, then retain actual full phase receipts. This operational review makes no new mathematical or machine-validation claim.
