N83 retained-base capacity result

2026-10-17 UTC. The primary `GF(2^83)` adapter accepted the retained K = 16,627 signed-Frobenius base and built an m = 4 identity-mask-zero orbit-domain model under one CPU, 4 GiB hard memory and zero swap.

The full worker completed with 201,598 SAT variables, 5,915,238 clauses and 3,901 XOR rows. Its cgroup peak was 2,661,126,144 bytes; exit 0, no OOM. The preregistered one-variable negative control returned `UNKNOWN_variable_cap` after exact-base import and preflight, also exit 0 without OOM. The input, binary, source and result digests are bound in `BUILD_RECEIPT.md`, `source-attestation.json`, `negative/worker.json` and `full/worker.json`.

This is a model-capacity result at the specified base and domain. SAT search, natural relations, useful rank, linear algebra, target extraction and complete cold cost remain open. The next gate is a degree-83 planted relation on this exact imported base. Full accounting and the baseline/rho gap are unchanged. See `RUN_REPORT.md` for hard caps, timings and limits.
